CONTENTS

EXECUTIVE SUMMARY	S-1
1. INTRODUCTION	1-1
1.1 Purpose of Report	1-2
1.2 Report Organization	1-2
2. SITE BACKGROUND	2-1
2.1 Site Description	2-1
2.2 Site History	2-1
2.2.1 Historical Operations	2-1
2.2.2 Environmental Restoration Responsibility	2-2
2.2.3 LEHR Federal Facility Potential Source Areas	2-2
2.3 Previous Investigations	2-3
2.3.1 Background Soil Investigations	2-3
2.3.2 LEHR Federal Facility Source Area Investigations	2-3
2.3.3 Ground Water Investigations	2-4
2.3.4 Storm Water, Surface Water and Sediment Investigations	2-4
2.3.5 Air Monitoring	2-6
2.3.6 Radiation Monitoring	2-6
2.3.7 Mixed Waste Storage Facility Closure	2-6
2.4 Previous Removal Actions	2-7
2.4.1 LEHR Federal Facility Source Area Removal Actions	2-7
2.4.2 Ground Water Interim Remedial Action	2-8
3. SITE PHYSICAL CHARACTERISTICS	3-1
3.1 Surface Features	3-1
3.1.1 Site Improvements	3-1
3.1.2 Surrounding Area Features	3-2

3.2	Meteorology	3-3
3.2.1	Precipitation	3-3
3.2.2	Wind Speed and Direction	3-3
3.3	Surface Water Hydrology	3-3
3.3.1	Putah Creek	3-3
3.3.2	Storm Water Runoff	3-4
3.3.3	Surface Water Quality	3-5
3.4	Geology	3-5
3.5	Vadose Zone Soils	3-5
3.6	Hydrogeology	3-6
3.6.1	Geologic Aspects	3-6
3.6.2	Hydraulic Aspects	3-7
3.6.3	Ground Water Quality	3-8
3.7	Demography and Land Use	3-8
3.7.1	Demography	3-8
3.7.2	Land Use	3-9
3.7.3	Surface and Ground Water Use	3-9
3.8	Ecology	3-10
3.8.1	Plant Communities	3-10
3.8.2	Wildlife	3-10
4.	SITE BACKGROUND CONCENTRATIONS, CONTAMINANT FATE AND TRANSPORT, AND PRELIMINARY RISK SCREENING	4-1
4.1	Site Background Concentrations	4-1
4.2	Constituent of Concern Identification	4-2
4.3	Risk-Based Action Standard Development	4-3
4.3.1	Fate and Transport Evaluation	4-3
4.3.2	Exposure Pathways and Scenarios	4-4
4.3.3	Risk Calculation	4-4
4.3.4	Risk Assessment Exposure Pathways and Scenarios	4-5
4.3.5	The On-Site Outdoor Researcher	4-5
4.3.6	The On-Site Indoor Researcher	4-6
4.3.7	The On-Site Construction Worker	4-6
4.3.8	The Hypothetical On-Site Resident	4-7
4.3.9	The Off-Site Farm Resident (East)	4-8

4.3.10 The Off-Site Farm Resident (South)	4-8
4.4 Designated-Level Analysis	4-9
5. DATA QUALITY EVALUATION	5-1
5.1 Data Usability Approach	5-1
5.2 Remedial Investigation Data Usability	5-1
5.2.1 Data Management	5-1
5.2.2 Data Validation and Review Pursuant to Data Quality Objectives	5-2
5.2.3 Data Assessment	5-2
5.3 Changes/Improvements in Methodology	5-4
6. NATURE AND EXTENT OF CONTAMINATION AND GROUND WATER IMPACT EVALUATION	6-1
6.1 Potential Source Evaluation and Removal Action Decision Process	6-1
6.2 Radium/Strontium Treatment Systems	6-3
6.2.1 Description and Operations	6-3
6.2.2 Pre-Removal Action Contaminant Distribution	6-3
6.2.3 Removal Action Summary	6-4
6.2.4 Post-Removal Action Contaminant Distribution	6-6
6.2.5 Ground Water Impact Evaluation	6-8
6.3 Domestic Septic Systems	6-10
6.3.1 Description and Operations	6-10
6.3.2 Domestic Septic Tank 1	6-10
6.3.3 Domestic Septic System 2	6-12
6.3.4 Domestic Septic System 3	6-12
6.3.5 Domestic Septic System 4	6-19
6.3.6 Domestic Septic Tank 5	6-21
6.3.7 Domestic Septic System 6	6-22
6.3.8 Domestic Septic System 7	6-26
6.3.9 Domestic Septic Systems 1 and 5 Leach Field (Dry Wells A through E)	6-26
6.4 Western Dog Pens	6-30
6.4.1 Description and Operations	6-30
6.4.2 Pre-Removal Action Contaminant Distribution	6-30
6.4.3 Removal Action Summary	6-31
6.4.4 Post-Removal Action Contaminant Distribution	6-32

6.4.5	Ground Water Impact Evaluation	6-34
6.5	Eastern Dog Pens	6-35
6.5.1	Description and Operations	6-35
6.5.2	Remedial Activity Summary	6-36
6.5.3	Contaminant Distribution	6-36
6.5.4	Ground Water Impact Evaluation	6-37
6.6	Southwest Trenches	6-38
6.6.1	Description and Operations	6-38
6.6.2	Pre-Removal Action Contaminant Distribution	6-39
6.6.3	Removal Action Summary	6-40
6.6.4	Post-Removal Action Contaminant Distribution	6-41
6.6.5	Ground Water Impact Evaluation	6-44
6.7	DOE Box	6-45
6.7.1	Description and Operations	6-45
6.7.2	Removal Action Summary	6-45
6.7.3	Post-Removal Action Contaminant Distribution	6-46
6.7.4	Ground Water Impacts	6-48
6.8	Storm Water, Surface Water and Sediment Investigations	6-49
6.8.1	Storm Water Monitoring	6-49
6.8.2	Putah Creek Investigations	6-50
6.8.3	Off-Site Cesium-137 Investigation	6-50
6.9	Air Monitoring	6-51
6.10	Environmental Radiation Dose Monitoring	6-52
7.	SUMMARY AND CONCLUSIONS	7-1
7.1	Nature and Extent of Soil Contamination	7-1
7.2	Potential Impact to Surface Water and Air	7-3
7.3	Plans for Additional Remedial Investigation Work	7-3
8.	REFERENCES	8-1

EXECUTIVE SUMMARY

The purpose of this Remedial Investigation (RI) Report is to summarize the results of all environmental investigations conducted at the Laboratory for Energy-Related Health Research (LEHR) Federal Facility in Davis, California. The LEHR Federal Facility Agreement (FFA) for the Site identifies the Southwest Trenches (SWT), the Radium/Strontium (Ra/Sr) Treatment Systems, the Western and Eastern Dog Pens (WDPs and EDPs), the Domestic Septic Systems (DSSs), and the United States Department of Energy (DOE) Disposal Box formerly used by the DOE for radiological studies as potential source areas for environmental releases. The LEHR land is owned by the Regents of the University of California (UC) and was used by DOE from 1958 through 1989. DOE is responsible for the environmental restoration of the LEHR Federal Facility, which was listed on the National Priorities List (NPL) in May 1994 as the LEHR/Old Campus Landfill in Davis, California. The University of California, Davis (UC Davis) is responsible for environmental restoration of the Old Campus Landfill areas of the NPL site. DOE is also responsible for monitoring storm water runoff from DOE areas. Based on a Memorandum of Agreement (MOA) between DOE and UC Davis, the Old Campus Landfill areas include three landfill disposal units, 49 waste holes, disposal trenches, ground water and Putah Creek. Because UC Davis Landfill Disposal Unit 2 underlies the LEHR Federal Facility EDPs, the remedy UC Davis implements to address this landfill will also address the EDPs. UC Davis and DOE are working on Draft MOA Amendment 1, which addresses the agreement for environmental restoration activities for this area.

For consistency with the FFA, the term "LEHR Federal Facility" is used in this RI report to refer only to those areas for which DOE has environmental restoration responsibility. The term "LEHR Site" refers to the area defined by the NPL as the LEHR/Old Campus Landfill site, which includes both the LEHR Federal Facility and the Old Campus Landfill areas. The term "LEHR" refers to the land and improvements located within the boundary line shown on Figure 1-2 of this document.

As an NPL site, the LEHR/Old Campus Landfill environmental restoration must be conducted in accordance with the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the National Contingency Plan (NCP), and Superfund guidance and policy. Therefore, this RI Report for the LEHR Federal Facility was prepared to fulfill the requirements of Section 300.430(b) of the NCP. UC Davis is preparing a separate RI report for its areas of responsibility in the Old Campus Landfill areas. UC Davis, with input from DOE, will use information from both RI Reports to prepare a Site-Wide Risk Assessment (SWRA) that addresses the risk presented by the combined LEHR/Old Campus Landfill Superfund Site. The results of this SWRA will be used to determine what, if any, additional remedial measures are needed to reduce risk to acceptable levels. Because a SWRA will be prepared as a separate document and will include both UC Davis and DOE source areas, this RI report deviates somewhat from the RI contents recommended in United States Environmental Protection Agency (US EPA) and DOE guidance in

that: 1) discussions on contaminant fate and transport evaluation and conceptual site model development are limited to DOE source areas; 2) constituents of concern (COCs) identified in this RI report are subject to change based on future risk assessment, and, 3) discussion of risk assessment is limited to a brief description of the risk-based action standards (RBASs) developed to guide removal actions (RAs). Although future risk assessment will replace them, the RBASs provide a useful reference for results presented in this RI.

LEHR is a 15-acre facility that contains laboratory buildings and former animal-handling facilities that were used by DOE. The Atomic Energy Commission (now DOE) began conducting radiological studies on laboratory animals, particularly beagles, in the early 1950s. Initial studies were carried out on the main UC Davis campus and involved the irradiation of beagles. DOE-funded research activities at LEHR began in 1958. Research at LEHR through the mid-1980s focused on the health effects from chronic exposure to radionuclides, primarily strontium-90 (Sr-90) and radium-226 (Ra-226). In the early 1970s, a cobalt-60 (Co-60) irradiator was constructed at LEHR to study the effects of chronic exposure to gamma rays on bone marrow cells of beagles. In 1975, DOE initiated a program at LEHR to study the potential health effects of combustion products from fossil fuel power plants. In 1983, the Toxic Pollutant Health Research Laboratory (TPHRL) began operating at LEHR.

All DOE-funded research activities at LEHR ceased by 1988. Environmental investigations began as early as 1984, building decontamination and decommissioning (D&D) began in 1992, and CERCLA RAs began in 1996. DOE plans to complete all LEHR Federal Facility environmental restoration activities by 2004. The potential contaminant source areas identified at the LEHR Federal Facility are: the Ra/Sr Treatment Systems, seven DSSs, WDPs and EDPs, the SWT disposal area, and the DOE Box disposal area. These areas have been the primary focus of DOE waste/soil investigations at the Site, and are the focus of this RI Report. In addition, DOE air and storm water investigations to evaluate site-wide impact from LEHR Federal Facility operations are also summarized. Ground water and surface water (Putah Creek) investigations conducted by UC Davis are also discussed as they relate to potential impact by LEHR Federal Facility sources.

To date, five RAs have been conducted at the LEHR Federal Facility: a time-critical RA in the DOE Box area, and non-time-critical RAs in the SWT, Ra/Sr Treatment Systems, WDPs, DSS 3 and DSS 6 areas. These RAs have eliminated significant waste and contaminated soil; therefore this RI Report bases conclusions on those data representative of post-RA conditions. However, pre-RA data collected after the LEHR Site was listed on the NPL and in accordance with CERCLA are also summarized, and additional data that were not collected under CERCLA are referenced as appropriate.

To help guide LEHR Federal Facility RAs, DOE conducted preliminary risk screening that included: 1) developing statistically-based, site-specific background concentrations for all constituents of concern (COCs) in soil; 2) developing RBASs for COCs in soil for three separate scenarios: on-site researcher, east residential farmer and south residential farmer; the RBAS development included fate and transport analysis, exposure pathway evaluations, exposure scenario development, and risk calculations; 3) setting the higher of background and lowest RBAS as the RA standards (RASs) for each COC; and, 4) conducting designated-level (DL) analysis to assess

potential impact to ground water by any residual COCs. Although the standards developed through this risk screening were specifically for guiding LEHR Federal Facility RAs, the approach used to develop the RASs is based on the US EPA Risk Assessment Guidance for Superfund (RAGS).

To evaluate the post-RA nature and extent of soil contamination, residual COC concentrations were compared to the site-specific RASs, US EPA Region 9 preliminary remediation goals (PRGs), and DL modeling results for ground water impact at background and maximum contaminant levels (MCLs). Potential ground water impact was also evaluated by comparing COC concentrations in ground water downgradient of each source area with background ground water concentrations. Results for the DOE source areas are summarized below.

- **Ra/Sr Treatment Systems**—The human health risk analysis using the site-specific RBAS indicates the cumulative cancer risk associated with Ra/Sr Treatment Systems area soil has been reduced to a nominal range of 10^{-4} to 10^{-6} and the non-cancer hazard quotient (HQ) for all COCs with the possible exception of mercury (Hg) were reduced below 1.0. The concentration distribution of driver COC Ra-226 in post-RA samples was indistinguishable from background. All Sr-90 concentrations were below the site-specific RBAS and industrial PRGs. The third driver COC, nitrate, was detected above background in only 8 of 68 samples, although several of these concentrations were significantly above background. No RBAS has been calculated for nitrate.

Based on DL analysis, nitrate and carbon-14 (C-14) remaining in soil in the Ra/Sr Treatment Systems area may impact local ground water above background and the MCLs. Ground water results from the nearest downgradient well suggest that actual impact, if any, from these COCs in Ra/Sr Treatment Systems area soil has been minimal..

- **WDPs**—Based on all CERCLA data, all significant contamination associated with the WDPs area has been removed. The human health risk analysis using the site-specific RBAS indicates the cumulative cancer risk has been reduced to a nominal range of 10^{-4} to 10^{-6} and the cumulative non-cancer HQ was reduced below 1.0. The concentration distribution of driver COC Ra-226 was indistinguishable from background. All Sr-90 concentrations were below the site-specific RBAS and industrial PRGs.

Based on DL analysis, it appears that COCs in WDPs soil have not, and should not in the next thousand years, have any significant impact on ground water.

- **EDPs**—Only Sr-90, chromium, hexavalent chromium (Cr-VI), seven pesticides, and two polychlorinated biphenyls (PCBs) were detected above background levels in EDPs soil. Of these, only the pesticide dieldrin exceeded its site-specific RBAS in one or more samples. Dieldrin also exceeded its residential and industrial PRGs in one or more samples. Chromium exceeded its residential PRG in two samples, but was below the site-specific RBAS and industrial PRG in all samples. Concentrations of all other above-background COCs in all samples were below both the site-specific RBASs, and residential PRGs. Based

on statistical analysis of the CERCLA data, all COCs in the EDPs soil are statistically below their respective RASs.

Based on DL analysis, it appears that COCs in EDPs soil have not, and should not in the next several thousand years, have any significant impact on ground water. Although a monitoring well immediately downgradient of the EDPs has elevated concentrations of three of the EDPs DL COCs (Cr-VI, chlordane, and dieldrin), these may be due to impact from UC Davis Landfill Disposal Unit 2 and the UC Davis disposal trenches east of the EDPs.

- DSSs—Based on all soil data representative of current conditions, the majority of the COCs in the vicinity of Domestic Septic Tank (DST) 1, DSS 4, DSS 5, DSS 7, and Dry Wells A through E are below their respective background and RBAS values. Following the RAs at DSS 3 and DSS 6, the cumulative excess cancer risk presented by remaining COCs in these areas is also below 10^{-6} . The calculated cumulative non-cancer HQs are 3.22 for DSS 3 and 2.5 for DSS 6, with Hg contributing almost all of the risk. DSS 7 was reportedly never used, and RI data support this understanding. DSS 2 was removed as part of the Ra/Sr Treatment Systems RA.

Based on soil results, DL modeling, and deionized water waste extraction test (DI WET) analyses, some COCs remaining in the DSS areas may impact local ground water above background, but the only potential impact above MCLs in the next thousand years is estimated to be by: formaldehyde and nitrate in the DSS 3 area; Cr-VI in the DSS 4 area; and, Cr-VI, chromium, Hg, and silver in the Dry Wells A through E area.

- SWT—The human health risk analysis using the site-specific lowest RBASs indicates the cumulative cancer risk has been reduced to a nominal range of 10^{-4} to 10^{-6} and the cumulative non-cancer HQ was reduced below 1.0. The concentration distribution of driver COC Ra-226 was indistinguishable from background. All Sr-90 concentrations were below the site-specific RBAS and industrial PRGs. Of those analytes statistically above background, only Hg was detected above its lowest RBAS, and no above-background analytes were detected above PRGs.

Based on DL analysis, only Cr-VI and nitrate remaining in SWT area soil may impact local ground water above MCLs within the next several thousand years. However, based on actual ground water data from the SWT area, there is no evidence of above-background impact to ground water by any of the DL COCs.

- DOE Box— Based on all soil data representative of current conditions, human health risk associated with the DOE Box area soil has been reduced to 10^{-5} or less. The cumulative non-cancer HQ was calculated to be 4.3, with Hg contributing 92 percent (%) of this figure.

Based on soil data, DL modeling, and DI WET analyses, COCs remaining in the DOE Box area are not likely to impact ground water above background for at least the next 3,000 years.

Eight metals and three pesticides have been detected above the lowest US EPA or California fresh water aquatic life criteria in one or more storm water samples collected from the LEHR Federal Facility. Of these constituents, only the pesticides and Hg are potentially related to DOE activities at LEHR. However, other sources of these COCs are also present both on-site and in the nearby areas that drain to Putah Creek. Because flow data for the LEHR discharge to Putah Creek have not been collected, the impacts of low levels of Hg and pesticides on Putah Creek are unknown.

All air and radiation monitoring data collected to date indicate that LEHR Federal Facility and related RA activities have had no significant impact on air.

Based on the data summarized in this document and the *Site-Wide Risk Assessment Work Plan* (UC Davis, 2002), DOE believes sufficient valid data are available for all DOE areas to complete the Site-Wide Risk Assessment (SWRA).

1. INTRODUCTION

The purpose of this Remedial Investigation (RI) Report is to summarize the results of all environmental investigations conducted at the Laboratory for Energy-Related Health Research (LEHR) Federal Facility in Davis, California (Figure 1-1). The LEHR FFA (United States Environmental Protection Agency Region 9 [US EPA], 1999a) identifies the Southwest Trenches (SWT), the Ra/Sr Treatment Systems, WDPs and EDPs, the DSSs, and the DOE Disposal Box formerly used by the DOE for radiological studies as potential source areas for environmental releases (Figure 1-2). DOE is responsible for the environmental restoration of the LEHR Federal Facility, which was listed on the National Priorities List (NPL) in May 1994 as the LEHR/Old Campus Landfill in Davis, California. As an NPL site, environmental restoration must be conducted according to the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), the NCP, and Superfund guidance and policy. Therefore, this RI Report was prepared to fulfill the requirements of Section 300.430(b) of the NCP. This report was prepared according to US EPA *Guidance for Conducting Remedial Investigations and Feasibility Studies Under CERCLA* (US EPA, 1988) and DOE's *Remedial Investigation/Feasibility Study Process, Elements and Techniques* (DOE, 1993), with consideration of the RI Statement of Work associated with the Administrative Order on Consent (AOC) issued to the University of California (UC) by the US EPA (US EPA Region 9, 1999b).

For consistency with the FFA and internally within this RI report, the following terms and definitions are used in this document:

- Constituents of Concern (COCs) – Chemical or radiological constituents in the environment that may result in adverse health or environmental impacts. COCs in this RI report were identified based on historical release information, characterization data and statistically-based background comparisons using US EPA protocols. The Site-Wide Risk Assessment (SWRA) will identify the final COCs for the DOE and UC Davis areas. The DOE Areas Feasibility Study Report will document any changes to COCs identified in this RI report.
- LEHR—As defined in the FFA, the land and improvements located within the boundary line on Figure 1-2.
- LEHR Site—As defined in the FFA, the area referred by the National Priorities List known as LEHR/Old Campus Landfill Superfund Site.
- LEHR Federal Facility—As specified in the FFA, the following areas at LEHR: those buildings listed under 4.m of the FFA; Co-60 irradiation field; SWT area; Ra/Sr Treatment Systems area; WDP and EDP areas; DSS areas; DOE Disposal Box area; and, areas where contamination originating from the areas listed above have come to be located, excluding areas assigned to the University of

California, Davis (UC Davis) by operation of the Memorandum of Agreement (MOA).

- DOE-funded research activities—All DOE-funded research activities at LEHR between 1958 and 1988.
- DOE RI Areas—Those areas of the LEHR Federal Facility identified as potential source areas, including the SWT area; Ra/Sr Treatment Systems area; WDP and EDP areas; DSS areas; DOE Disposal Box area; and, Mixed Waste Storage Facility (MWSF).
- UC Davis RI Areas—Those areas for which UC Davis has accepted responsibility, as defined in the FFA, including: UC landfill cells beneath the LEHR facility; Landfills 1, 2 (exclusive of dog pens), and 3; the 49 waste holes; ground water; and the UC Davis disposal trenches (south and east of Landfill 2).

1.1 Purpose of Report

The purpose of this RI Report is to summarize the results of all remedial investigations conducted at the LEHR Federal Facility. One time-critical and four non-time-critical removal actions (RAs) have been conducted at the LEHR Federal Facility that have eliminated significant waste and contaminated soil. Therefore this RI bases conclusions on those data representative of post-RA conditions. However, pre-RA data collected after the LEHR Federal Facility was listed on the NPL and in accordance with CERCLA are also summarized, and additional data that were not collected under CERCLA are also referenced as appropriate.

The primary purpose of an RI under CERCLA is to provide the information needed to assess the risk posed by the Site and to determine the best way to reduce that risk to acceptable levels. This information includes: 1) the nature and extent of the contamination; 2) physical characteristics that could affect contaminant fate and transport (i.e., surface features, meteorology, surface water hydrology, geology, and hydrogeology); and, 3) potential receptors (i.e., demography, land use, and ecology). This information is also used to assess threats to surface water and ground water. For the LEHR/Old Campus Landfill Superfund Site, DOE is responsible for remediating the LEHR Federal Facility and UC Davis is responsible for remediating the Old Campus Landfill sites. DOE and UC Davis are each preparing an RI Report that addresses the areas for which they have cleanup responsibility. UC Davis, with input from DOE, will use information from both RI Reports to prepare a SWRA that addresses the risk presented by the combined LEHR/Old Campus Landfill Superfund Site. The results of this SWRA will be used to determine what, if any, additional remedial measures are needed to reduce risk to acceptable levels.

1.2 Report Organization

This report is organized as recommended in US EPA and DOE guidance (US EPA, 1988; DOE, 1993), with modifications that reflect *Task 3: Remedial Investigation of the Statement of Work*

for Remedial Investigation/Feasibility Study (Appendix B of the AOC, US EPA Region 9, 1999b). Its organization is also based on input from the LEHR Site Remedial Project Managers (RPMs), including US EPA Region 9 staff. Because an SWRA will be prepared as a separate document and will include both UC Davis and DOE RI Areas, this RI report deviates somewhat from the RI contents recommended in US EPA and DOE guidance in that: 1) discussions on contaminant fate and transport evaluation and conceptual site model development are limited to DOE RI Areas; 2) constituents of concern (COCs) identified in this RI report are subject to change based on future risk assessment, and, 3) discussion of risk assessment is limited to a brief description of the RBASs developed to guide removal actions. Although future risk assessment will replace them, the RBASs provide a useful reference for results presented in this RI.

In addition to this introduction, the report includes:

- Section 2—Site Background. This section briefly describes the LEHR Site and a history of site use prior to, during, and after DOE's occupancy. It also summarizes and provides references to previous environmental investigations and remedial activities that are relevant to the LEHR Federal Facility. Details of these activities are presented by source area in Section 6.
- Section 3—Site Physical Characteristics. In accordance with US EPA and DOE guidance, this section describes the surface features, meteorology, surface water hydrology, geology, soils, hydrogeology, demography/land use, and ecology of the LEHR Site and the surrounding area. This information may, in large part, be presented in the UC Davis RI Report, but is included here for completeness. This information has been used by DOE and will be used in the SWRA for evaluating contaminant fate and transport, potential exposure pathways, and potential receptors.
- Section 4—Site Background Concentrations, Contaminant Fate and Transport, and Preliminary Risk Screening. This section summarizes the approach, methodology, and results for the preliminary risk screening DOE has conducted to guide LEHR Federal Facility RAs. This includes: 1) development of statistically-based, site-specific background concentrations for all COCs; 2) development of RBASs, which includes fate and transport analysis, exposure pathway evaluations, exposure scenario development, and risk calculations; and, 3) DL analysis, which focuses on contaminant transport to ground water. Although the standards developed through these processes were specifically for guiding LEHR Federal Facility RAs, the approach used to develop the RBASs is based on that described in RAGS (US EPA, 1989 and 1991) and remains useful as a preliminary risk benchmark for the LEHR Site. Final cleanup levels will be based on the results of the SWRA.
- Section 5—Data Quality Evaluation. This section summarizes data validation results and data usability.
- Section 6—Nature and Extent of Contamination and Ground Water Impact Evaluation. This section describes the nature and extent of contamination and

potential ground water impact associated with the LEHR Federal Facility. The first subsection (Section 6.1) indicates which areas within the LEHR Federal Facility were identified as potential sources that have impacted the environment and describes the overall RA decision process used for these source areas. For each potential source area, the subsequent subsections summarize the: 1) LEHR Federal Facility operations and environmental investigations in that area; 2) RA activities and air monitoring results for that area; 3) nature and extent of contamination associated with that area, both prior to and after any RAs; and, 4) potential impact to ground water by COCs remaining in that area. Site-wide sediment, surface water, storm water, air, and environmental radiation dose data related to the LEHR Federal Facility are also discussed in this section.

- Section 7—Summary and Conclusions. This section presents conclusions regarding the nature and extent of contamination and DOE's preliminary assessment of risk associated with the LEHR Federal Facility. Potential RI data gaps are also identified.
- Section 8—References. This section lists references for locating detailed information on the individual investigations that compose the LEHR Federal Facility RI.

Figures and tables referenced within a section are located at the end of that section. Details of the data usability evaluation are included in Appendix A. Details on the recent DSSs Investigations are provided in the technical memorandum that is included as Appendix B of this RI Report. Results of DL screening for DSSs are presented in Appendix C. Air monitoring data collected at the LEHR Site are presented and discussed in Appendix D. All LEHR Federal Facility RI laboratory analytical data are included on compact disk in Appendix E. The human health risk analysis for the DOE Box area is presented in Appendix F. Appendix G includes tables summarizing the Non-Isothermal, Unsaturated-Saturated Flow and Transport (NUFT) model input parameters and results of the modeling conducted for the DOE Areas. The Phase A DL analyses for the Ra/Sr Treatment Systems and SWT areas were re-run with the addition of valid investigation data that represent current site conditions. The Phase A DL summary tables for Ra/Sr Treatment Systems and SWT areas are presented in Appendix H. The maximum concentration of all of the COCs detected above background in the waste characterization data for each area are presented in Appendix I. The de-ionized water waste extraction test (DI WET) and grab ground water results for the DL samples collected in the DSS and DOE Box areas are presented in Appendix J. A list of acronyms and abbreviations used in this RI report is included immediately following the table of contents.

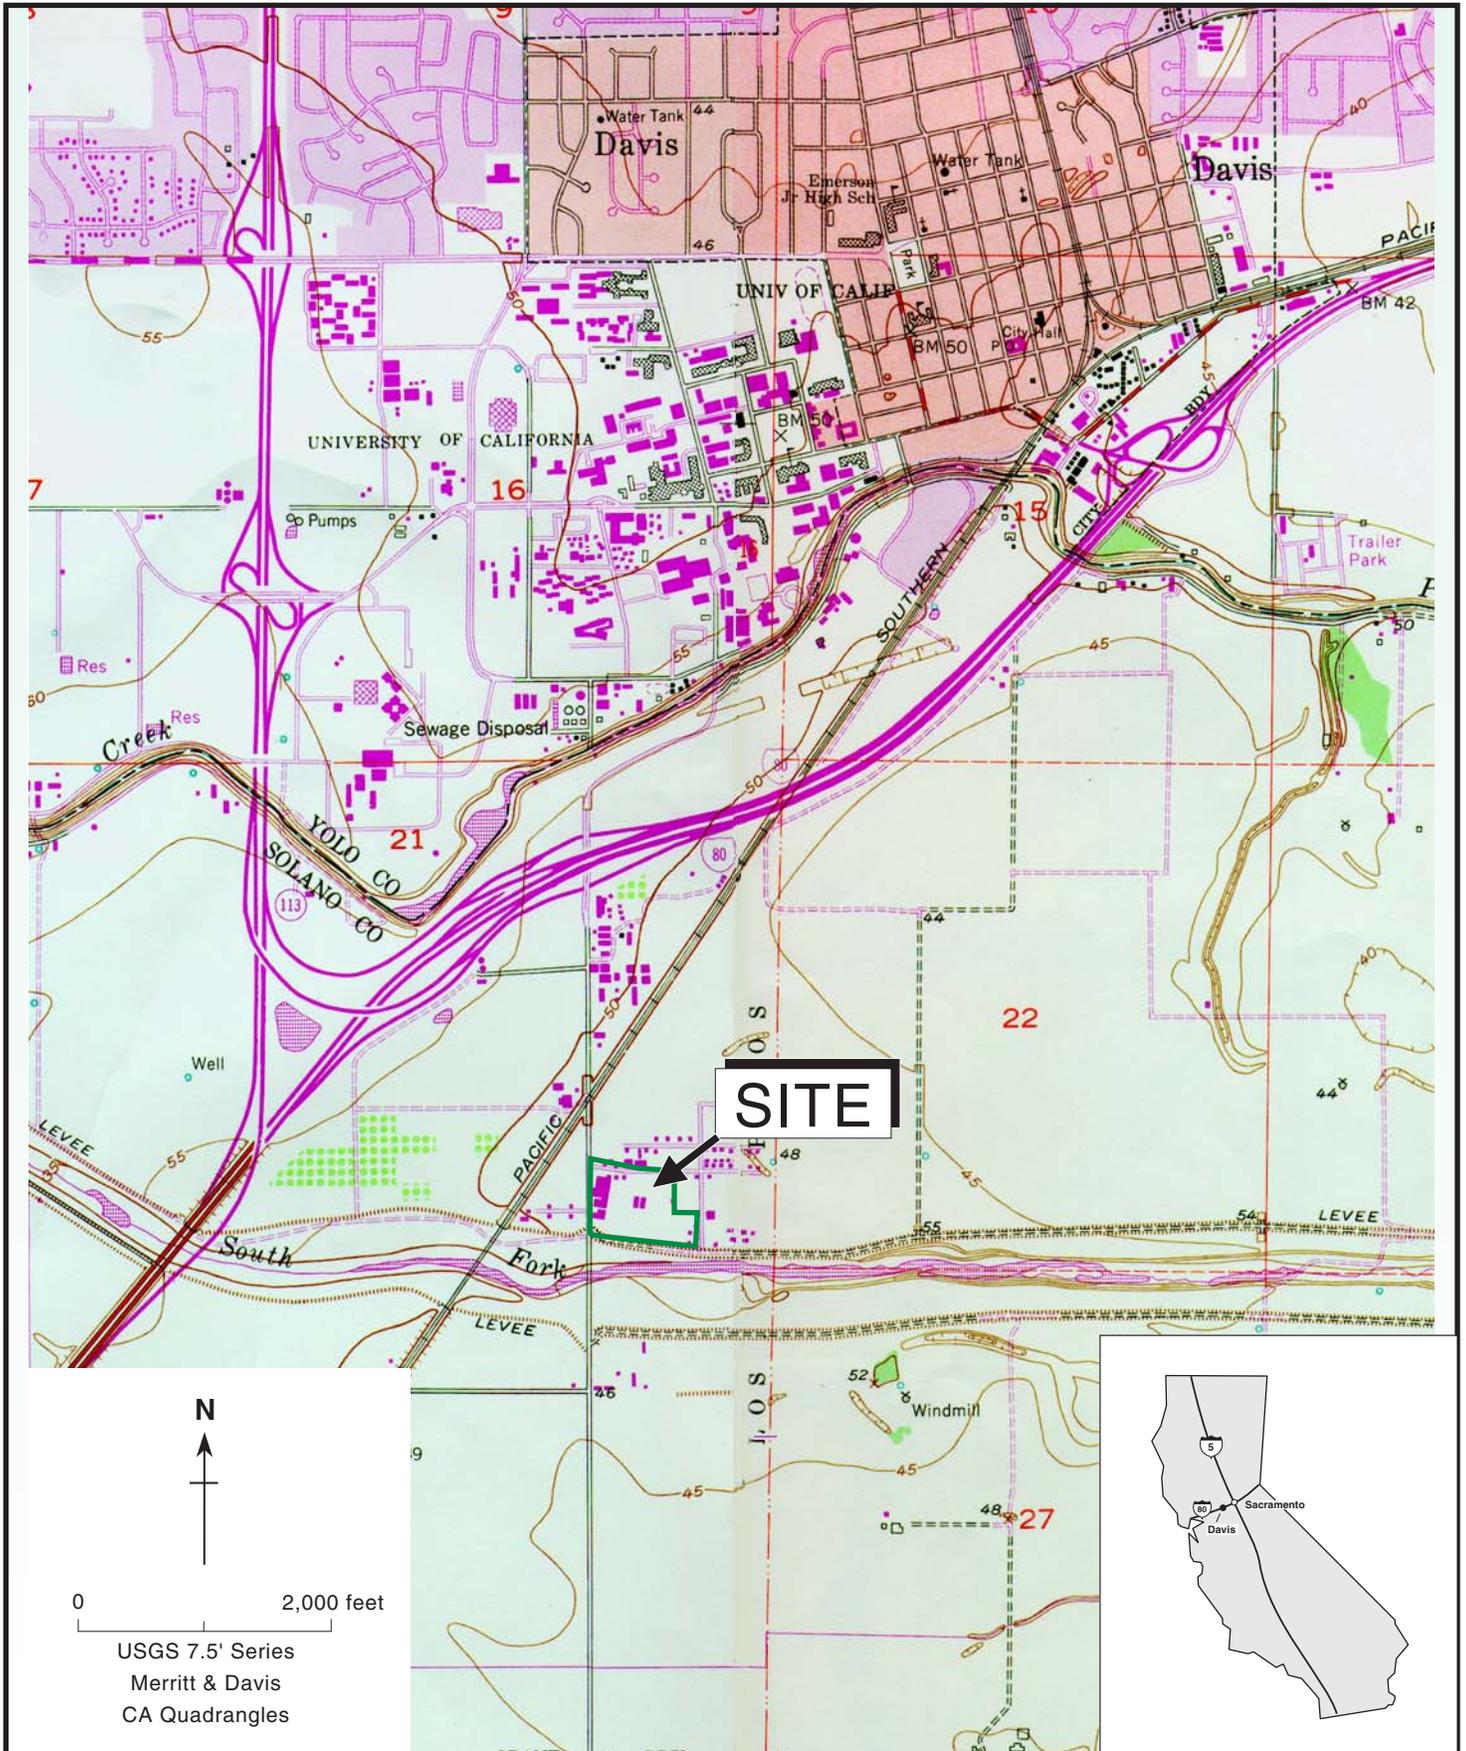

Figure 1-1. Location of the LEHR Site, UC Davis, California

Weiss Associates

Figure 1-2. LEHR Site Features and Potential Contamination Source Areas

Weiss Associates

2. SITE BACKGROUND

2.1 Site Description

The LEHR Site is located in Solano County, California, in the southeast quarter of Section 21, Township 8 North, Range 2 East, Mount Diablo Base and Meridian (Figure 1-1). It is approximately 1.5 miles south of the town of Davis and is bounded by UC Davis research facilities, private farmland, and the South Fork of Putah Creek. The southern boundary of the LEHR Site is the northern levee of the South Fork of Putah Creek.

LEHR covers approximately 15 acres and contains laboratory buildings and former animal-handling facilities that were used by DOE. Figure 1-2 shows the spatial distribution of buildings at LEHR. Of the 15 acres, approximately 40 % is paved or covered by structures. Approximately 30 % is unpaved and relatively free of vegetation. Five percent is covered by large, deep-rooted vegetation. Outdoor dog pens occupied approximately 20%, or three acres, of LEHR. The land is owned by the Regents of UC and was used by DOE from 1958 through 1989. Part of LEHR is presently utilized by the UC Davis Center for Health and the Environment (CHE) for research activities.

2.2 Site History

2.2.1 Historical Operations

A chronology of activities at the LEHR Federal Facility is presented in Figure 2-1. For the period prior to DOE's use of LEHR, aerial photographs from 1937, 1952, and 1957 were reviewed to determine site conditions and usage. In 1937, the LEHR location was primarily open grassland with scattered brush and trees, and was similar to the agricultural land in the surrounding area. Remnants of an apparent golf course were visible mainly on the eastern half of the LEHR location. Additionally, a small structure was present within a group of trees along the southern boundary adjacent to the South Fork of Putah Creek. By 1952, the former golf course and structure were absent and much of the vegetation at the LEHR location appeared to have been cleared or grazed on by cattle. By 1957, new roads had been established in the southern portion of the LEHR location and there was evidence of grading or excavation activities in the EDPs area. It should be noted that UC Davis operated two landfills within the boundaries of LEHR: Landfill Disposal Unit 1 from the early 1940s through mid-1950s and Landfill Disposal Unit 2 from 1956 through 1967 (Figure 1-2), for exclusive disposal of UC Davis waste.

The Atomic Energy Commission (now DOE) began conducting radiological studies on laboratory animals, particularly beagles, in the early 1950s. Initial studies were carried out on the main UC Davis campus and involved the irradiation of beagles. DOE-funded research activities began at LEHR in 1958. DOE-funded research at LEHR through the mid-1980s focused on the health effects from chronic exposure to radionuclides, primarily Sr-90 and radium-226 (Ra-226). In the early 1970s, a cobalt-60 (Co-60) irradiator facility was constructed by DOE at LEHR to study the effects of chronic exposure to gamma rays on bone marrow cells of beagles. In 1975, DOE initiated a program at LEHR to study the potential health effects of combustion products from fossil fuel power plants. In 1983, the Toxic Pollutant Health Research Laboratory (TPHRL) became operative at LEHR. Studies at TPHRL included the use of americium-241 (Am-241) and plutonium-241 (Pu-241).

All DOE-funded research activities at LEHR had ceased by 1988. Environmental investigations began as early as 1984, building D&D began in 1992, and CERCLA RAs began in 1996. DOE plans to complete all environmental restoration activities related to the LEHR Federal Facility by 2004.

2.2.2 Environmental Restoration Responsibility

Based on historical use, DOE and UC Davis have developed a MOA to allocate responsibility for environmental restoration of the LEHR/Old Campus Landfill Superfund Site (DOE, 1997). Under this agreement, DOE is responsible for environmental restoration of the former LEHR Federal Facility, as described in Section 1. UC Davis is responsible for environmental restoration of Old Campus Landfill areas including but not limited to: Landfill Disposal Units 1, 2 and 3; the 49 waste holes; the UC Davis disposal trenches; ground water; and, Putah Creek (Figure 1-2). Because Landfill Disposal Unit 2 underlies the EDPs, the remedy UC Davis implements to address this landfill will also address the EDPs. UC Davis and DOE are currently working on Draft MOA Amendment 1, which addresses the agreement for environmental restoration activities for the Landfill Disposal Unit 2/EDPs area.

2.2.3 LEHR Federal Facility Potential Source Areas

The following areas of the LEHR Federal Facility have been identified as potential source areas: Ra/Sr Treatment Systems, seven DSSs, WDPs and EDPs, the SWT disposal area, and the DOE Disposal Box area (Figure 1-2). As discussed in Section 6.1, these areas have been the focus of remedial investigations at the facility. A description of each of these areas and its operations is presented by area in Section 6.

2.3 Previous Investigations

This section summarizes all environmental investigations related to the LEHR Federal Facility. Details of the investigation results related to specific source areas and/or media of concern are presented in Section 6.

2.3.1 Background Soil Investigations

There have been five separate sampling events to collect background soil data. Table 2-1 summarizes these investigations and Figure 2-2 shows the sample locations associated with them. As described in Section 4.1, the analytical results from these investigations were used to develop statistically-based background levels for all COCs for the LEHR Federal Facility. These background levels were then used to determine which COCs were potentially present above background in each of the LEHR Federal Facility source areas. For COCs with a calculated RBAS lower than the background level (Section 4.1), the background level was used as the removal action standard (RAS).

2.3.2 LEHR Federal Facility Source Area Investigations

Contaminant investigations in LEHR Federal Facility potential source areas are described in detail by area in Section 6 and are briefly summarized here. In 1984, an Initial Assessment Survey was conducted by Rockwell International to obtain data and perform an initial characterization of the nature and extent of radioactive and chemical contamination at the LEHR Site. Surface and subsurface investigations were conducted in all of the DOE potential source areas except the DSS and DOE Box areas (Rockwell, 1984).

From late 1987 through 1988, Wahler Associates conducted investigations to determine potential low-level radioactive sources at the LEHR Federal Facility. Surface and subsurface investigations were conducted in the SWT, Ra/Sr Treatment Systems area, WDPs and EDPs areas, and vicinity of the DOE Box (Wahler, 1989). Between 1989 and 1993, Dames and Moore (D&M) conducted several investigations to evaluate the potential source areas at the LEHR Site. In 1995, Pacific Northwest National Laboratory (PNNL) conducted surface and subsurface investigations in the SWT and at DSS 2. Surface and subsurface investigations were conducted in all of the DOE potential source areas except for the DSS and DOE Box areas (D&M, 1991; D&M, 1993).

In 1996, IT Corporation (IT Corp.) conducted a Limited Field Investigation (LFI) to collect data necessary to evaluate if potential sources associated with the LEHR Federal Facility pose an unacceptable threat to human health and the environment. The LFI included investigations of the SWT area, Ra/Sr Treatment Systems area, and DSSs 1 and 7 [Weiss Associates (WA), 1997f.] In 1996, IT Corp. also removed the WDP and EDP pedestals and collected soil and gravel data during the removal activities (WA, 1997f). From 1996 to 2001, WA conducted several data gaps investigations to collect additional data on the DSSs, WDPs and EDPs (WA, 1998c; 1998d and 1999c).

Many of the data from these investigations were collected prior to the issuance of the *Remedial Investigation, Feasibility Study and Environmental Assessment Work Plan in September 1994* (D&M, 1994) and may not have been collected in full compliance with CERCLA standards. Data collected before the D&M Phase II Investigation in 1993 were obtained to screen for contamination; therefore, these results are considered to be qualitative only. Dog pen data from 1996 were collected primarily for health and safety rather than for characterization purposes. Therefore, data from the LFI, subsequent data gaps investigations, and post-RA sampling, which were conducted in compliance with CERCLA requirements, are emphasized in this report. The nature and extent of contamination in the LEHR Federal Facility potential source areas (DOE RI Areas) based on these data are discussed in Section 6.

2.3.3 Ground Water Investigations

The first ground water investigation at the LEHR Site was conducted in 1987. The *Water Monitoring Plan* (PNNL, 1994) has been the basis of ground water monitoring since 1994. Since then, 21 wells have been installed in the shallowest hydrostratigraphic unit (HSU)-1, 18 wells have been installed in HSU-2, and 5 wells in HSU-4 (Figure 2-3). No wells have been installed in HSU-3. Ground water investigation activities conducted to date are summarized in Table 2-2. Hydrogeologic findings based on these investigations are summarized in Section 3.6.

Ongoing ground water monitoring of selected wells has occurred since 1990. In 1997, the MOA between DOE and UC Davis transferred responsibility for ground water and surface water sampling from DOE to UC Davis. Ground water analytical results, proposed monitoring plan changes, and the rationale for these changes are presented in annual water monitoring reports (D&M, 1999c and 2000; URS, 2001). The LEHR Site ground water chemical and radionuclide analytical data, as they relate to potential impact by LEHR Federal Facility sources, are discussed by source area in Section 6.

2.3.4 Storm Water, Surface Water and Sediment Investigations

2.3.4.1 Storm Water Monitoring

The original site storm water monitoring plan (described in PNNL, 1994) was established in the fall of 1994. From 1994 through 1996, field measurements and samples of storm water runoff were collected by DOE at two locations where storm water collects and is removed from LEHR. One collection point (SWL-1, now called Lift Station [LS]-1) is a lift station located on the west side of LEHR (Figure 2-3), which pumps runoff from much of the western part of LEHR under Old Davis Road for discharge into Putah Creek. The second collection point was a storm drain (SWL-2, now called SD-1) located on the west side of the WDPs area that collects storm water from the west-central portion of LEHR, primarily from the paved areas east of the buildings (Figure 2-4).

In the winter of 1996-1997, location SD-1 was eliminated because water flowed from this location to LS-1 (Figure 2-4), which was already being sampled. Also during this time, two

additional locations were added: landfill-1 (LF)-1 located south of Landfill Unit 1, and LF-3 located south of Landfill Unit 3. As of 1997, in accordance with the MOA between DOE and UC Davis (DOE, 1997), DOE collects storm water only from LS-1, and UC Davis collects storm water from the UC Davis areas of the LEHR Site (LF-1 and LF-3 in Figure 2-3).

The monitoring plan specifies sampling for two separate rainfall events: (1) the first significant storm event of the rainy season; and, (2) a large storm event late in the rainy season. The initial storm water samples were analyzed for the following during the two sampling events in 1995 and 1996: selected radionuclides, metals, Cr-VI, nitrate, alkalinity, other cations and anions, volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), formaldehyde, pesticides, PCBs, total oil and grease, suspended and dissolved solids, total organic carbon, chemical oxygen demand, and turbidity.

Alkalinity, other cations/anions, SVOCs, and formaldehyde have been removed from the original storm water analyte list (D&M, 1998). SVOCs and formaldehyde were removed because they had not been detected. Aquatic toxicity was added, and it may include alkalinity, hardness, dissolved oxygen, pH and ammonia (D&M, 1998). Also low-level mercury (Hg) analysis was added. Storm water monitoring results are summarized in Section 6.8, and recent results are discussed in detail in the annual water monitoring reports (D&M, 1999c and 2000; URS, 2001).

2.3.4.2 Surface Water Monitoring

The surface water monitoring program at the LEHR Site began in November 1990, and through 1996 was conducted quarterly by DOE at three locations along the South Fork of Putah Creek: Putah Creek Upstream (PCU), Wastewater (Sewage) Treatment Plant Outfall (STPO), and Putah Creek Downstream (PCD) (Figure 2-3). Starting in the first quarter of 1997, UC Davis began performing the surface water monitoring. In 2000, UC Davis collected surface water samples from four locations: PCU, STPO, PCD, and PC2 located approximately two miles downstream of PCD (Figure 2-3). Putah Creek monitoring data are summarized in Section 6.8.2, and more detailed discussions of these data can be found in the annual water monitoring reports (D&M, 1999c and 2000; URS, 2001).

2.3.4.3 Sediment and Related Investigations

In addition to the storm and surface water monitoring described above, several related investigations have been conducted at the LEHR Site. Between August and September 1996, the Agency for Toxic Substances and Disease Registry (ATSDR) collected four composite samples each of Putah Creek fish, sediments, and water to determine if the LEHR Site activities have impacted the creek. The fish, sediment, and water samples were analyzed for radionuclides, metals, pesticides, and SVOCs (ATSDR, 1997). Results are summarized in Section 6.8.2.

Because of known overflows of the Ra-226 Treatment System that may have resulted in wastewater discharge into the storm water drainage channels along Old Davis Road (Figure 2-4), several investigations of shallow sediments in these channels were performed. Initial investigations in 1996 and 1997 (WA, 1997f and 1998d) evaluated a wide range of potential contaminants. Based on the results of these two investigations, the final investigation in 1998 focused on cesium-137

(Cs-137) as the only COC in these sediments (WA, 1999f). Results of these investigations are discussed in Sections 6.2.2 and 6.8.3.

2.3.5 Air Monitoring

In 1995, an air monitoring program was developed and implemented by PNNL. A comprehensive air quality study was conducted in 1995 and 1996 (PNNL, 1996a). Additional "baseline" air monitoring was conducted in 1997 and 1998. During each of the four DOE RAs conducted at the LEHR Federal Facility between 1998 and 2001, air monitoring was conducted to assess airborne impacts during the RA activities (WA, 2001c, WA 2001e). RA air monitoring results are summarized in Section 6 by source area, and Figure 2-5 shows the air sampling locations. The air monitoring investigations are summarized in Table 2-3. Air monitoring results are discussed in detail in Appendix D.

2.3.6 Radiation Monitoring

Perimeter fence lines, radioactive waste storage areas, and various work areas around the LEHR Site are monitored for gamma radiation by thermoluminescent dosimeters (TLDs) to comply with DOE Orders 5400.1, *General Environmental Protection Program*, and 5400.5, *Radiation Protection of the Public and the Environment*. This radiation monitoring program began in 1989 with 35 TLD locations. In the fourth quarter 1995, the number of TLDs was reduced to 25 after completion of the D&D of the Animal Hospitals (AH) and Specimen Storage Buildings. Figure 2-7 shows the locations of the 24 TLDs currently used at the LEHR Site. The 25th TLD is a control monitoring station located in the Environmental Safety and Health Building on the UC Davis campus. The radiation monitoring is ongoing and is summarized on a yearly basis in the Annual Site Environmental Report (ASER) for the LEHR Site. An overall summary of results is presented in Section 6.10.

2.3.7 Mixed Waste Storage Facility Closure

The MWSF (Figure 2-6) was a prefabricated steel structure and is not considered one of the LEHR Federal Facility buildings. The MWSF was used to store hazardous and radioactive mixed waste from the DOE-funded research at the LEHR Site. This facility was designed to store hazardous or mixed waste/materials and to provide sound environmental protection against contamination due to spills or leaks (WA, 1999d). The MWSF was operated by UC Davis for DOE under the Resource Recovery and Conservation Act (RCRA) interim permit application status issued by the US EPA. Following the conclusion of the DOE-funded research program in 1988, numerous legacy waste streams were removed from the MWSF and disposed off-site at appropriately permitted facilities. Therefore, the MWSF was no longer needed to store mixed wastes and was closed in 2000 according to a California Department of Toxic Substances Control (DTSC)-approved closure plan (EMS, 1997). The MWSF was transferred to UC Davis following proper closure.

Radiological and chemical verification samples were collected from the MWSF structure and underlying surface soil as part of the MWSF closure process. At the request of DTSC, the surface soil and asphalt under and around the MWSF were sampled to determine whether a release of contaminants occurred from the MWSF to the environment (WA, 1999d). A “direct frisk” radiological survey was conducted over 100% of the facility’s asphalt “footprint,” and radiological smears for loose surface contamination were collected at 16 points within the “footprint”. Wipe samples were collected from the secondary containment trays of each storage unit and analyzed for VOCs, SVOCs and formaldehyde. Although not required, soil sampling was conducted beneath the MWSF as a conservative measure to ensure cleanup. Sample results showed that constituents of potential concern in soil under and around the unit were at or below the US EPA Region 9 PRGs and/or site-specific background concentrations.

Based on data presented in the *Closure Certification Report* (WA, 1999d) as well as that in Section 3 of the *MWSF Summary Data Report* (WA, 1999e), residuals remaining on the facility surfaces and soils did not exceed the closure performance standards. The *Closure Certification Report* concluded that:

- Each of the closure performance standards in the closure plan had been achieved;
- Clean closure was obtained; and,
- The surfaces of the MWSF are well below the radiological release limits presented in DOE Order 5400.5 for unrestricted use.

The *Closure Certification Report* was approved by DTSC on March 22, 2000, and the ownership of the MWSF was transferred from DOE to UC Davis on April 17, 2001. The LEHR MWSF closure is discussed in greater detail in the *Closure Certification Report* (WA, 1999d) and the *Summary Data Report* (WA, 1999e).

2.4 Previous Removal Actions

2.4.1 LEHR Federal Facility Source Area Removal Actions

As discussed in Section 6.1, the potential contaminant source areas identified at the LEHR Federal Facility are: the Ra/Sr Treatment Systems area, the DSSs areas, the WDPs and EDPs areas, the SWT area, and the DOE Box area. To date, DOE has conducted one time-critical and four non-time-critical RAs. Each of the completed RAs is summarized in Section 6 of this RI. The time-critical RA was the removal of the DOE Box in 1996. The four non-time critical RAs were the SWT area RA in 1998, the Ra/Sr Treatment Systems Area I and II RAs in 1999 and 2000, the WDPs area RA in 2001, and the DSS 3 and 6 area RA in 2002. DST 2 and parts of the DSSs 1 and 5 leach field were removed during the Ra/Sr Treatment Systems area RA. No RAs are anticipated for the remaining DSSs. The EDPs and underlying UC Davis Landfill Disposal Unit 2 will be remediated together by UC Davis.

2.4.2 *Ground Water Interim Remedial Action*

On May 11, 1998, UC Davis began full-scale operation of the ground water interim remedial action (IRA) extraction and treatment system. The ground water IRA is being conducted by UC Davis in accordance with the US EPA Action Memorandum (November 13, 1997) and the MOA between UC Davis and DOE (June 23, 1997) (D&M, 1999b). The IRA was implemented to minimize the off-site migration of VOCs, primarily chloroform. The IRA consists of extracting ground water from HSU-2 downgradient of site source areas (well EW2-1, Figure 2-3), treating the ground water for VOCs by air stripping, and injecting treated water into HSU-2 upgradient of the LEHR Site (well IW2-1, Figure 2-3). Through December 2000, 169,479,676 gallons of ground water had been treated by the system, removing an estimated 65.25 pounds of chloroform.

A density-driven convection (DDC) well pilot test was conducted from December 12, 2000 to March 21, 2001 to assess whether DDC technology effectively reduces chloroform mass in the shallow ground water (HSU-1) system. According to URS (2001), the chemical and hydraulic data collected during the pilot test demonstrate the development of active circulation, the capture and removal of chloroform from ground water, and the reduction or elimination of downward vertical migration of impacted ground water from HSU-1 to HSU-2. Based on the results of the DDC pilot test, the system may be expanded.

Table 2-1. Previous LEHR Background Investigations

Date	Characterization Activity	Document Reference ⁽¹⁾
February 1993	Twelve soil samples were collected from the off-site monitoring wells UCD2-17 and UCD1-18. The samples were analyzed for radionuclides, metals, and inorganic compounds. <i>Not performed under CERCLA.</i>	D&M, 1993
1994	Twenty-four soil samples were collected to depths of 39 ft bgs at six locations within one-half mile of LEHR. The samples were analyzed for radionuclides, metals and inorganic compounds. <i>CERCLA investigation.</i>	D&M, 1994
October 1997	Fifty-two samples were collected to depths of 40 ft bgs from six locations and analyzed for selected radionuclides and metals. Approximately 25 of these samples were also analyzed for volatile organic compounds, semi-volatile organic compounds, and organochlorine pesticides. <i>CERCLA investigation.</i>	WA, 1998c
February 1999	Forty soil samples were collected from the surface and 2 ft bgs in 20 locations. The samples were analyzed only for constituents showing depth stratification based on the 1994 and 1997 data. <i>CERCLA investigation.</i>	WA, 2000a-e
October through December 1999	Three shallow soil samples were collected from previous background boring locations. The samples were analyzed for mercury compounds or species by a lab that specializes in these analyses. In addition, two shallow soil samples from previous background locations were collected and analyzed for total mercury by two other laboratories to evaluate elevated mercury detected at these locations during the February 1999 investigation. <i>CERCLA investigation.</i>	WA, 1999, a-f

Table 2-2. Previous LEHR Ground Water Investigations

Date	Characterization Activity	Document Reference ⁽¹⁾
1987	Installation of five monitoring wells in HSU-1 (UCD1-1, UCD1-3 through UCD1-6) and one in HSU-2. Soil samples from UCD1-1 were submitted and analyzed for gross alpha, beta, gamma, tritium and strontium-90. <i>Not performed under CERCLA.</i>	Wahler, 1989
1987	Installation of two monitoring wells in HSU-1 (UCD1-8 and UCD1-9). <i>Not performed under CERCLA.</i>	Wahler, 1989
1989	Four monitoring wells were installed in HSU-1 (UCD1-10 through UCD1-13) and one monitoring well in HSU-2 (UCD2-14). Soil samples were collected from UCD1-10 through UCD1-13 and analyzed for VOCs, SVOCs, pesticides, PCBs, metals, nitrate, and selected radionuclides. <i>Not performed under CERCLA.</i>	D&M, 1990a
1989	Samples were collected from nearby privately owned wells, the UC Davis Wastewater Treatment Plant outfall and downstream of the UC Davis Wastewater Treatment Plant outfall. The samples were analyzed for nitrate and hexavalent chromium. <i>Not performed under CERCLA.</i>	D&M, 1990b
1990	Installation of seven monitoring wells in HSU-1 (UCD1-18 through UCD 1-24) and three monitoring wells in HSU-2 (UCD2-15 through UCD2-17). <i>Not performed under CERCLA.</i>	D&M, 1993
1995	Installation of two monitoring wells in HSU-1 (UCD1-25 and UCD1-34), two monitoring wells in HSU-2 (UCD2-26 and UCD2-35), and one monitoring well that has seven screened intervals across HSU-1 and HSU-2 (UCD1-27/2-27). <i>CERCLA investigation.</i>	PNNL, 1996b
1996	Hydropunch investigation conducted at ten onsite locations and 12 off-site locations. Each location sampled at 85 and 95 ft bgs and samples analyzed for chloroform, chromium, nitrate, and specific conductivity. <i>CERCLA investigation.</i>	D&M presentation at April 1996 RPM meeting
1996	Installation of one monitoring well in the first HSU (UCD1-28) and three monitoring wells and one extraction well in HSU-2 (UCD2-29 through UCD2-31 and EW2-1). <i>CERCLA investigation.</i>	D&M, 1996
1997	Installation of six monitoring wells in HSU-2 (UCD2-32 and UCD2-36 through UCD2-40), three monitoring wells in HSU-4 (UCD4-41 through UCD4-43), and one injection well in HSU-2 (IW2-1). <i>CERCLA investigation.</i>	D&M, 1998

Table 2-3. Previous LEHR Air Monitoring Investigations

Date	Characterization Activity	Document Reference ⁽¹⁾
1995-1996	Baseline sampling—Airborne contaminants were sampled by four continuously operating on-site samplers and at one distant location. The samples were analyzed for radionuclides, radon, chlordane, metals, VOCs, and airborne dust.	PNNL, 1996a
1997-1998	Site monitoring—Airborne contaminants were sampled at four on-site and one off-site location bimonthly and analyzed for gross alpha and gross beta. Gamma emitters and radon were also analyzed in some samples.	Not previously reported. See Appendix D of this report.
1998	SWT RA monitoring—Air monitoring samples were collected from four fixed locations and a mobile monitoring station at the SWT area. The samples were analyzed for gross alpha and beta, tritium, radon, metals, VOCs, and SVOCs.	WA, 2001e
1999	Ra/Sr Treatment Systems Phase I RA Monitoring—Air monitoring samples were collected from four fixed locations and a mobile monitoring station at the Ra/Sr Treatment Systems area. Pre-RA, post- RA and monthly RA samples were collected and analyzed for one or more of the following: PM ₁₀ , metals, VOCs, chlordane, tritium, gross alpha, gross beta and gamma-emitting isotopes.	WA, 2001c
2000	Ra/Sr Treatment Systems Phase II RA Monitoring—Air monitoring samples were collected from four fixed locations and a mobile monitoring station at the Ra/Sr Treatment Systems area). Pre-RA, post-RA and monthly RA samples were collected and analyzed for PM ₁₀ ; metals; Sr-90; and gross alpha, beta, and gamma.	WA, 2001c
2001	WDPs RA—Air monitoring samples were collected from four fixed locations and a mobile monitoring station at the WDPs area. Pre-RA, post-RA and monthly samples were collected and analyzed for PM ₁₀ ; metals; Sr-90; and gross alpha, beta, and gamma.	WA, 2002c
2002	DSS 3 and 6 RA—Air monitoring samples were collected from four fixed locations and a mobile monitoring station near DSS 6. Samples were collected during one sampling event and analyzed for barium, cadmium, Cs-137, chlordane, chromium, copper, heptachlor epoxide, Pb, Pb-210, Hg, Ra-226, silver, Sr-90 and PM ₁₀ .	WA, 2002a

3. SITE PHYSICAL CHARACTERISTICS

This section describes the physical setting of the LEHR Site, including topography, structures, meteorology, geology, hydrogeology, surface water hydrology, land use and demographics, and ecology. Information provided in this section was used in the preliminary risk screening analyses described in Section 4.

3.1 Surface Features

The LEHR Site is situated on gently sloping land, with an average elevation of approximately 50 feet (ft) above mean sea level. The land surface slopes gently to the east/northeast at approximately 0.001 ft/ft (five ft per mile). Relief across LEHR is about two ft.

3.1.1 Site Improvements

Approximately 40% of the 15-acre LEHR is paved or covered by structures. The former outdoor WDPs and EDPs occupied approximately three acres or 20% of LEHR. Prior to the RAs about 30% was unpaved and relatively free of vegetation and less than 5% was covered by large, deep-rooted vegetation.

The improvements used for DOE-funded research activities at LEHR consisted of mainly single-story laboratory buildings, former animal-handling facilities, and outdoor dog pens (Figure 1-2). The facility also housed a Co-60 Irradiator Building and an associated irradiation field. The facilities used for DOE-funded research activities are described in greater detail in Section 6.

Most of the buildings used at LEHR for DOE-funded research activities are now used by the UC Davis CHE. In 1975, the fencing, dog house installations, gravel and interior curbing were removed from 64 pens in the northern section of the WDPs. In 1996, the dog house installations, interior fencing and concrete pedestals were removed from the remainder of the WDPs and the EDPs for proper disposal. The barrels and concrete pedestals were properly packaged and shipped to the DOE Hanford site for disposal. In 1999 the interior chain-link fencing was released from radiological controls according to DOE Order 5400.5 and recycled off-site. In 2001, the gravel, exterior fencing and remaining curbing were removed from the WDPs for proper disposal. The concrete and asphalt were disposed at Nevada Test Site (NTS) and the Altamont Class II Disposal Facility in Livermore, respectively. The remaining material removed during the 2001 RA is currently being stored on-site in two covered stockpiles.

In 1995, the Imhoff Building, which housed the Ra/Sr Treatment Systems, was decontaminated, decommissioned and demolished. Between 1999 and 2000, the Sr-90 (former Imhoff Tank) and Ra-226 Treatment Tanks, along with associated potentially contaminated soil, gravel and piping and their adjoining leach fields, were excavated and removed. The overburden removed during the 1999 RA was used as backfill in the 2000 RA excavation. The soil and debris removed during the 1999 RA was disposed as low-level waste (LLW) at Envirocare of Utah in 2001. The sludge and debris removed from the Sr-90 Tank were shipped to Hanford for disposal as LLW. The Sr-90 Tank storm water was solidified and sent to Envirocare of Utah as solid LLW in 2002. The remaining waste was shipped to NTS in 2002 for disposal.

All seven DSSs and leach fields associated with DOE-funded research activities were abandoned in 1971 and have been replaced by direct sanitary sewer connections. DST 2 and dry wells associated with DSS 1 and DSS 5 were removed in 1999 as part of the Ra/Sr Treatment Systems Area I RA. The DST 2 waste was disposed with the Ra/Sr 1999 waste stream. The DSS 1 and 5 waste was disposed at NTS in 2002. RAs were conducted at DSS 3 and 6 during 2002. The DSS 3 RA consisted of removal of a distribution box (DB), effluent lines, leach lines, leach trench gravel and one foot of additional soil from the leach trench floor and sidewalls. The DSS 6 RA consisted of removal of all the effluent lines, perforated Orangeburg pipe and leach trench gravel. An additional foot of soil was also removed from the trench floors and sidewalls. The DSS 3 and 6 waste is currently being stored on-site for pending characterization results.

Disposal trenches and chlordane-contaminated soil in the southwestern part of the Site (SWT area) were excavated in 1998. The SWT hazardous waste was treated and disposed by Safety Kleen, Diversified Scientific Services Incorporated and Envirocare of Utah. In addition, the trench repository used for disposal of miscellaneous LLW associated with DOE-funded research (e.g., syringes, bottles, vials and gravel), referred to as the DOE Box, has been excavated and disposed at the DOE Hanford site.

3.1.2 Surrounding Area Features

The land within a one-mile radius of LEHR is owned both privately and by the Regents of UC, and is used for animal research, agriculture and recreation. Immediately east, north and west of LEHR are UC Davis-owned research facilities. Privately owned lands within one mile to the south and east of LEHR include permanent residences and fields that support some crops. Approximately 75% of the surrounding land in the general vicinity of LEHR is used for agriculture. Major crops include fruits, nuts and grains. Approximately 40% of the agricultural land in the LEHR vicinity is irrigated and some of the nearby lands are used for cattle grazing (DOE, 1988). Recreational land uses in this area primarily involve fishing and swimming along nearby Putah Creek.

3.2 Meteorology

The LEHR area climate is temperate, with mild winters and long warm summers. In winter, the average temperature is 46.7 degrees Fahrenheit (°F), the average daily minimum temperature is 37.5°F and the average maximum temperature is 55.9°F. The lowest daily temperature of 12°F was recorded in December 1932. The average summer temperature is 73.0°F, with the highest daily average of 91.8°F. The highest recorded temperature of 116°F occurred in July 1925 (Western Regional Climate Center Website, 2002).

3.2.1 Precipitation

The average annual precipitation at the Davis 1 west southwest station, located less than two miles northwest of LEHR, is 17.31 inches based on data from 1917 to 2000. Between 1917 and 2000, the highest and lowest monthly average precipitation were 12.48 inches in January 1995 and 0.02 inches in February 1964, respectively. Based on data from 1917 to 2000, the highest recorded rainfall during the winter (December, January and February) was 22.98 inches in 1993 (Western Regional Climate Center Website, 2002).

3.2.2 Wind Speed and Direction

The prevailing wind direction is from the south (Figure 3-1), reflecting frequent incursions of marine air through the Carquinez Strait into the Sacramento Valley. Changes in wind direction are common, with winds from the northwest occurring diurnally. Several times a year, strong winds blow from the north, generally following the passage of Pacific storm systems (DOE, 1994). The average 2000 wind speed recorded at the LEHR 3-meter tower was approximately 1.23 meters per second (m/s) or 2.75 miles per hour (mph), the maximum wind speed was 6.44 m/s (14.4 mph) and the median wind speed was 1.12 m/s (2.5 mph) (WA, 2001i). Figure 3-1 is a wind rose generated from data collected at the Sacramento Airport.

3.3 Surface Water Hydrology

No natural or man-made surface or recreational waters are present at LEHR or upstream of the LEHR site.

3.3.1 Putah Creek

Putah Creek, the only surface water body near the LEHR site, is described below. Putah Creek was redirected to what is now called the “South Fork” in 1872. The “South Fork” of Putah Creek is about 125 ft south of LEHR within a man-made channel (Figure 2-3) to divert flood waters

from the City of Davis and the UC Davis main campus. The channel is separated from the LEHR boundaries by a one-lane, paved roadway on top of a levee completed in 1948 by the US Army Corps of Engineers. The South Fork of Putah Creek is an intermittent stream, sometimes containing only scattered pools during the dry summer months. In the past, drought conditions have resulted in the lower portions going dry and in significant fish and invertebrate animal kills (Marchetti and Moyle, 1995). The creek is typically bordered by dense vegetation and small trees within and adjacent to the channel.

LEHR is in Federal Emergency Management Administration Zone C. The area is expected to experience minimal flooding. As shown on federal flood maps, the 100-year flood plain is confined within the Putah Creek levees at the southern LEHR boundary.

Putah Creek is a “losing” stream (a portion of its flow recharges ground water). Flow in the South Fork of Putah Creek is regulated by releases from Monticello Dam at Lake Berryessa and from the Putah Diversion Dam, located about 18 and 14 miles west of LEHR, respectively. Based on data from 1980 through 1991, flows several miles upstream from LEHR typically range from 0.1 cubic ft per second (cfs) to about three cfs, although flows as high as 15,500 cfs (in March 1983) have been reported (D&M, 1994). In the reach bordering LEHR, flow in the South Fork of Putah Creek is supplemented by discharge from the UC Davis Wastewater Treatment Plant. Based on data from a gauge near Old Davis Road, flow rates for the reach bordering LEHR ranged from 0.17 to 148 cfs from 1989 to 1993. In May 2002, a settlement known as the “Putah Creek Accord” was reached between the Solano County Irrigation District, UC Davis and others. The settlement provides minimum flows for the lower 23 miles of the creek during non-drought years.

Former mercury mining above Lake Berryessa, which is located upstream of the LEHR Site and Putah Creek, may be the source of mercury detected in Putah Creek sediments and in shallow site soil.

3.3.2 Storm Water Runoff

As shown in Figure 2-4, storm water runoff at LEHR is collected in surface and subsurface drainage systems. The majority of the storm water from the paved areas on the western part of the site is collected in catch basins and routed to the LEHR storm water lift station-1, (Figure 2-4). This storm water is discharged to an unlined ditch on the east side of Old Davis Road, where it ponds temporarily and travels through a culvert to an unlined ditch on the west side of Old Davis Road. Precipitation that falls along the eastern and non-paved southern portions of LEHR, including most of the SWT and the former WDPs and EDPs, infiltrates into the soil. Drainage for a section of the former Co-60 Field where dog pens were once located is connected to the sanitary sewer. Water ponds during heavy rains in some areas at LEHR, including the former WDPs and EDPs.

3.3.3 Surface Water Quality

Direct sampling of surface water in Putah Creek is conducted by UC Davis as part of its CERCLA responsibilities (Section 2.2.2). Putah Creek water quality and its relation to potential impacts from the LEHR Federal Facility are summarized in Section 6.8.2.

3.4 Geology

LEHR and vicinity are in the Putah Plain of the Sacramento Valley (Department of Water Resources [DWR], 1978), which consists of alluvial fan deposits associated with Putah Creek. These alluvial sediments consist primarily of silt and clay with localized, interfingered, coarse-grained sediments and are approximately 180 ft thick (DWR, 1978). Beneath LEHR, the sediments are nearly flat-lying and conformably overlie the Tehama Formation, which consists of silts and clays with discontinuous lenses of coarse sands and gravel and is the principal water-bearing geologic unit on the west side of the Sacramento Valley. Figure 3-2 is a block diagram showing the site hydrogeology.

The depths and types of major sedimentary units encountered in boreholes beneath LEHR are described below from youngest to oldest. Some of the units contain gradational sequences or more than one lithology.

- 0 to 80 ft—Interbedded silt, clay and sand with some sand and gravel channel deposits. The surficial soil is underlain by interbedded clay, silty clay, silt and sand. This fine-grained interval is fairly continuous across LEHR and contains some coarse sand and gravel. The ground water table occurs in this stratigraphic unit and varies in depth from approximately 15 to 65 ft below ground surface (bgs), depending on the season and total rainfall.
- 80 to 135 ft—Cobbles and gravel. Well-rounded cobbles and gravel are encountered approximately 80 ft bgs and appear to be laterally continuous beneath most of LEHR. Where present, this unit is approximately 35 to 52 ft thick.
- 135 to 143 ft—Clay and some silt. Clay and silt underlie the cobbles and gravel. The top of this clayey unit is encountered at depths ranging from 120 to 137 ft bgs (D&M, 1993).

3.5 Vadose Zone Soils

The surface soil at LEHR has been mapped as Reiff fine sandy loam in the Soil Survey of Solano County, California (United States Department of Agriculture [USDA], 1977). These soils are relatively young and weakly developed. The “A” horizons are relatively thick and organic-rich, and therefore ideal for agriculture (USDA, 1977). Surface soils have been disturbed in some areas of

LEHR, including the EDPs and Rows A and B of the former WDPs, as a result of subsurface excavation and construction activities.

The vadose zone extends from the ground surface to the top of ground water table, which has historically ranged from 15 to 65 ft bgs. The vadose zone consists primarily of unsaturated clay and silt with lesser amounts of interbedded sand and gravel.

In 1996, nine vadose zone soil samples collected at various depths for geotechnical testing were analyzed by Daniel B. Stephens and Associates, Inc. for moisture content, bulk density, porosity, saturated and unsaturated hydraulic conductivity, moisture characteristics and particle density. In general, the results were consistent with the silty clay to clay soil type observed in the field. The physical measurement ranges are described below:

- Gravimetric moisture contents ranged from 2.2% to 23.8% by weight;
- Dry bulk densities ranged from 1.51 to 1.92 grams per cubic centimeter (g/cm^3);
- Calculated porosities ranged from 29.3% to 43.6%; and,
- Saturated hydraulic conductivities ranged from 4.7×10^{-3} centimeters per second (cm/sec) to 1.0×10^{-8} cm/sec (D.B. Stephens & Associates, 1996).

The hydraulic conductivities that were used in LEHR vadose zone modeling were not based on the DB Stephens results. Rather, they were based on more conservative literature values for a given sediment type and ranged from 1.0×10^{-4} cm/sec for sand to 1.0×10^{-6} cm/sec for clayey sandy silt.

To provide information for evaluation of potential remedial alternatives in the EDPs area, four surface and four two- ft bgs soil samples were collected and analyzed for bulk density, porosity, and moisture content in 1999. The results of these analyses are:

- Moisture contents ranged from 5.8 to 20.1% by weight;
- Bulk densities ranged from 1.5 to 1.96 g/cm^3 ; and,
- Calculated porosities ranged from 35.0 to 43.6% (WA, 1999c).

3.6 Hydrogeology

3.6.1 Geologic Aspects

Unconsolidated Pliocene and Pleistocene deposits are the major ground water sources for public and private water supplies in the Sacramento Valley (DWR, 1978). Both unconfined and confined fresh water aquifers are present in these sedimentary deposits in the uppermost 3,000 ft of the valley subsurface.

Previous investigations have identified five HSUs beneath the LEHR Site (D&M, 1999c): the vadose zone and HSUs 1 through 4. The vadose zone extends from the ground surface to the top of ground water, which has historically ranged from 15 to 65 ft bgs. The vadose zone consists primarily of unsaturated clay and silt with lesser amounts of interbedded sand and gravel. HSU-1 extends from the bottom of the vadose zone to a depth of approximately 76 to 88 ft bgs. This unit is lithologically similar to the vadose zone and consists primarily of silt and clay, with lesser amounts of sand and gravel. HSU-2 extends from the bottom of HSU-1 to a depth of approximately 114 to 130 ft bgs. This unit is composed primarily of sand in the upper portion of the unit and gravel in the middle to lower portions of the unit. HSU-3, investigated in off-site areas, extends from the bottom of HSU-2 to a depth of about 250 ft bgs and is approximately 120 ft thick. The unit consists primarily of relatively fine-grained sediments varying from very fine-grained sandy silt to clayey silt and silty clay. HSU-4, investigated in off-site areas, extends from the bottom of HSU-3 to a depth of about 282 ft bgs and is approximately 32 ft thick. This unit consists of coarse sand and gravel. Beneath HSU-4, a sharp contact with a bluish, dark gray silt was encountered at 282 ft bgs in wells UCD4-41 and UCD4-43. The bottom of this unit was not penetrated in any of the LEHR Site borings (D&M, 1999c).

The uppermost distinct aquifer beneath the LEHR Site has been divided into two HSUs (HSU-1 and HSU-2), based on stratigraphy and the associated ground water flow and contaminant migration characteristics (D&M, 1994). Well drillers' logs indicate that a 90-ft-thick clay unit separates HSU-2 from a second aquifer below (D&M, 1994). Based on hydrostratigraphic cross sections presented in the *2000 Annual Groundwater Monitoring Treatment System and Water Monitoring Report*, HSU-1 and HSU-2 represent the Putah Creek fan and HSU-3, HSU-4 and the dark bluish gray silt beneath HSU-4 represent the Tehama Formation (URS, 2001).

3.6.2 Hydraulic Aspects

In the vicinity of the LEHR Site, ground water generally flows east from the Coast Ranges toward the Sacramento River (D&M, 1993). The HSU-1 lateral gradient across the LEHR Site typically ranges from 0.01 to 0.04 ft/ft, predominantly to the northeast. Representative values of HSU-1 horizontal hydraulic conductivity are between 1×10^{-4} and 1×10^{-7} cm/sec (D&M, 1999c). The lateral HSU-2 gradient across the LEHR Site typically ranges from 0.005 ft/ft to 0.015 ft/ft and is predominantly northeast, although it can occasionally be east-southeast. Based on pumping tests, hydraulic conductivity in HSU-2 ranges from 0.26 to 0.43 cm/sec (D&M, 1997). Not enough data are available for HSU-3 and HSU-4 to evaluate lateral gradient magnitude and direction or hydraulic conductivity ranges.

Generally, there is a 20- to 30-ft seasonal fluctuation in the depth-to-ground water beneath the LEHR Site caused predominantly by agricultural pumping in the summer. Vertical gradients vary both temporally and spatially. In 2000, vertical gradients were downward during the summer due to agricultural pumping and fairly neutral during the winter months. In the summer of 2000, the hydraulic head difference between HSU-1 and HSU-2 was 2.86 ft and the head difference between HSU-2 and HSU-4 was 38.7 ft (URS, 2001). Figures 3-3 and 3-4 show the seasonal ground water elevation contours for HSU-1 and HSU-2, respectively.

Irrigation, rainfall and Putah Creek recharge ground water in the vicinity of the LEHR Site (D&M, 1997). Ground water pumping associated with agricultural and municipal supply is largely responsible for ground water withdrawal. UC Davis extraction well EW2-1 only affects the HSU-2 horizontal gradient in the vicinity of the well, which is located downgradient of the LEHR Site. UC Davis is also injecting water in HSU-2 at injection well IW2-1, upgradient of LEHR. This injection activity also only affects the horizontal gradient in the vicinity of the well.

3.6.3 Ground Water Quality

There is a total of 44 monitoring wells on and around the LEHR Site that monitor HSU-1, HSU-2 and/or HSU-4 (Figure 2-3). Ground water samples from these wells and hydropunch locations provide information on ground water characteristics and quality. Additional ground water quality data are available from agricultural and domestic water wells in the surrounding areas.

The underlying ground water contains total dissolved solids (TDS) between 392 milligrams per liter (mg/l) and 1,710 mg/l, with the lowest concentration in HSU-4 and the highest concentration in HSU-1. The TDS ranges for each HSU are: 472 mg/l (UCD1-18) to 1,710 mg/l (UCD1-12) in HSU-1, 428 mg/l (UCD2-37) to 910 mg/l (UCD2-14) in HSU-2, and 392 mg/l (UCD4-44) to 549 mg/l (UCD4-47) in HSU-4 (URS, 2001). Regional water quality has been impacted by the presence of nitrates due to agricultural sources, and Cr-VI, probably from natural sources (D&M, 1990b; UC Davis, 1997). Ground water in HSUs 1 and 2 also has been impacted by past LEHR Site activities. Waste disposal by UC Davis is the likely source of chloroform, C-14 and tritium in ground water. However, sources for other COCs have not been determined. The potential impact of LEHR Federal Facility sources on ground water is discussed by source area in Section 6..

At various depths beneath the valley floor, fresh water gives way to saline water as a result of entrapment during the deposition of sediments in a marine environment. The depth to the base of fresh water in the Sacramento Valley is 2,600 to 3,100 ft bgs in the Davis area [Division of Oil and Gas (DOG), 1982]. The occurrence and characteristics of ground water beneath the LEHR Site have been summarized in numerous reports (WA, 1997f; D&M, 1999c; and PNNL, 1996b).

3.7 Demography and Land Use

3.7.1 Demography

LEHR is part of the Davis/UC Davis community. The main UC Davis campus and the City of Davis (downtown area) are located 1.2 and 1.9 miles, respectively, north of LEHR (Figure 3-5). UC Davis has a 3,600-acre campus and research area, has a student population of approximately 26,094, and employs approximately 16,773 full-time faculty and staff based on fall 2000 figures (UC Davis Website, 2002). The current population of Davis is approximately 60,308 and the current population of Yolo County is over 168,660 (U.S. Census Bureau, 2002). In 1999, the total

employment in Yolo County was 86,200 with government providing 31.9% (27,500) of those jobs. The City of Davis has approximately 21,000 housing units. The average population density in the counties surrounding LEHR ranges from 112 to 806 people per square mile. Agriculture is a small fraction of total employment.

Many of the buildings used for DOE-funded research activities at LEHR in the past are currently occupied by the CHE program. CHE has 14 resident and 13 affiliate faculty members, and 9 support staff, and houses the Division of Reproductive Biology, UC Agricultural Health & Safety Center, and IR-4 research programs.

3.7.2 *Land Use*

LEHR is designated as “Urban and Built-Up Land” by the State of California Department of Conservation for Yolo and Solano Counties Important Farmlands Maps (UC Davis, 1997). Specific land uses for LEHR and the immediate adjacent areas are under the control of UC Davis and are consistent with the UC Davis long-range development plans (UC Davis, 1997).

As shown on Figure 3-5, land in the immediate vicinity of LEHR is either part of the UC Davis campus or used for agriculture. Immediately adjacent to LEHR are the UC Davis Raptor Center and animal research facilities. The Raptor Center primarily houses raptors that have been injured or orphaned. Additionally, an unrestricted outdoor area containing a burrowing owl project is located about 1,500 ft east of LEHR. Other UC Davis animal research includes horses, cows, goats and other domesticated farm animals located in outdoor corrals and pens. Agricultural land is south of Putah Creek and east and west of property owned by UC Davis. Wheat, tomatoes, corn, barley and oats are mainly grown on this agricultural land.

Future land use plans for the surrounding areas outside of UC Davis do not identify significant changes, with the exception of development of a light industrial area about one mile north of LEHR near I-80 and within the boundaries of the City of Davis. According to UC Davis, LEHR use will remain research-oriented for the foreseeable future.

3.7.3 *Surface and Ground Water Use*

3.7.3.1 **Drinking Water Intakes and Distribution**

LEHR Site ground water is not currently used for drinking water or other direct human use, nor is it expected to be used for these purposes in the future. Drinking water is supplied to LEHR by the campus water system, which is supplied by five deep wells; the nearest well, DW-4, is about 400 ft north of LEHR. The screened interval for domestic water production well DW-4 is 1,120 to 1,400 ft bgs, well below the depth of contamination beneath the LEHR Site.

There are 19 municipal wells within four miles of LEHR, serving approximately 47,500 people (US EPA, 1994a). Six domestic water supply wells and six agricultural water supply wells are

located in the vicinity of the LEHR Site. Bottled water is being supplied temporarily to some local residents as a precautionary measure.

3.7.3.2 Water Recreational Areas

The South Fork of Putah Creek is used for recreational activities such as fishing, swimming, rafting and other related water activities. The creek and channel with its dense vegetation and trees constitute an open space area that provides habitat for birds and small wildlife.

3.8 Ecology

The biological resources discussed here are plant communities and wildlife. Detailed information on the plant communities and wildlife has been gathered to develop an Ecological Scoping Assessment for LEHR (WA, 1997a). The subsections below summarize existing site plants and wildlife. All plant and animal species known or expected to occur on-site or nearby are listed in Tables B-1 and B-2 of the *Draft Final Ecological Scoping Assessment* (WA, 1997a).

3.8.1 Plant Communities

Areas of LEHR not covered by buildings, structures and pavement support ruderal vegetation (e.g., weeds), non-native grassland, landscaping (primarily horticultural trees) and bare ground. Habitats include ruderal/non-native grassland, buildings and structures and ruderal/landscape ornamental trees. The locations within LEHR that do not fall within one of these three habitats are few and sparse but may be foraged. No naturally occurring special-status communities occur at or immediately adjacent to LEHR, including the South Fork of Putah Creek and the channel it lies within.

Special-status species are those species of plants and animals defined under the Endangered Species Act (50 Code of Federal Regulations [CFR] 17.12), California Endangered Species Act (14 CFR 670.5) and those considered sufficiently rare by the scientific community to qualify for such a listing. No special-status species of plants were detected or have been recorded at LEHR or the surrounding region within approximately a one-mile radius of LEHR.

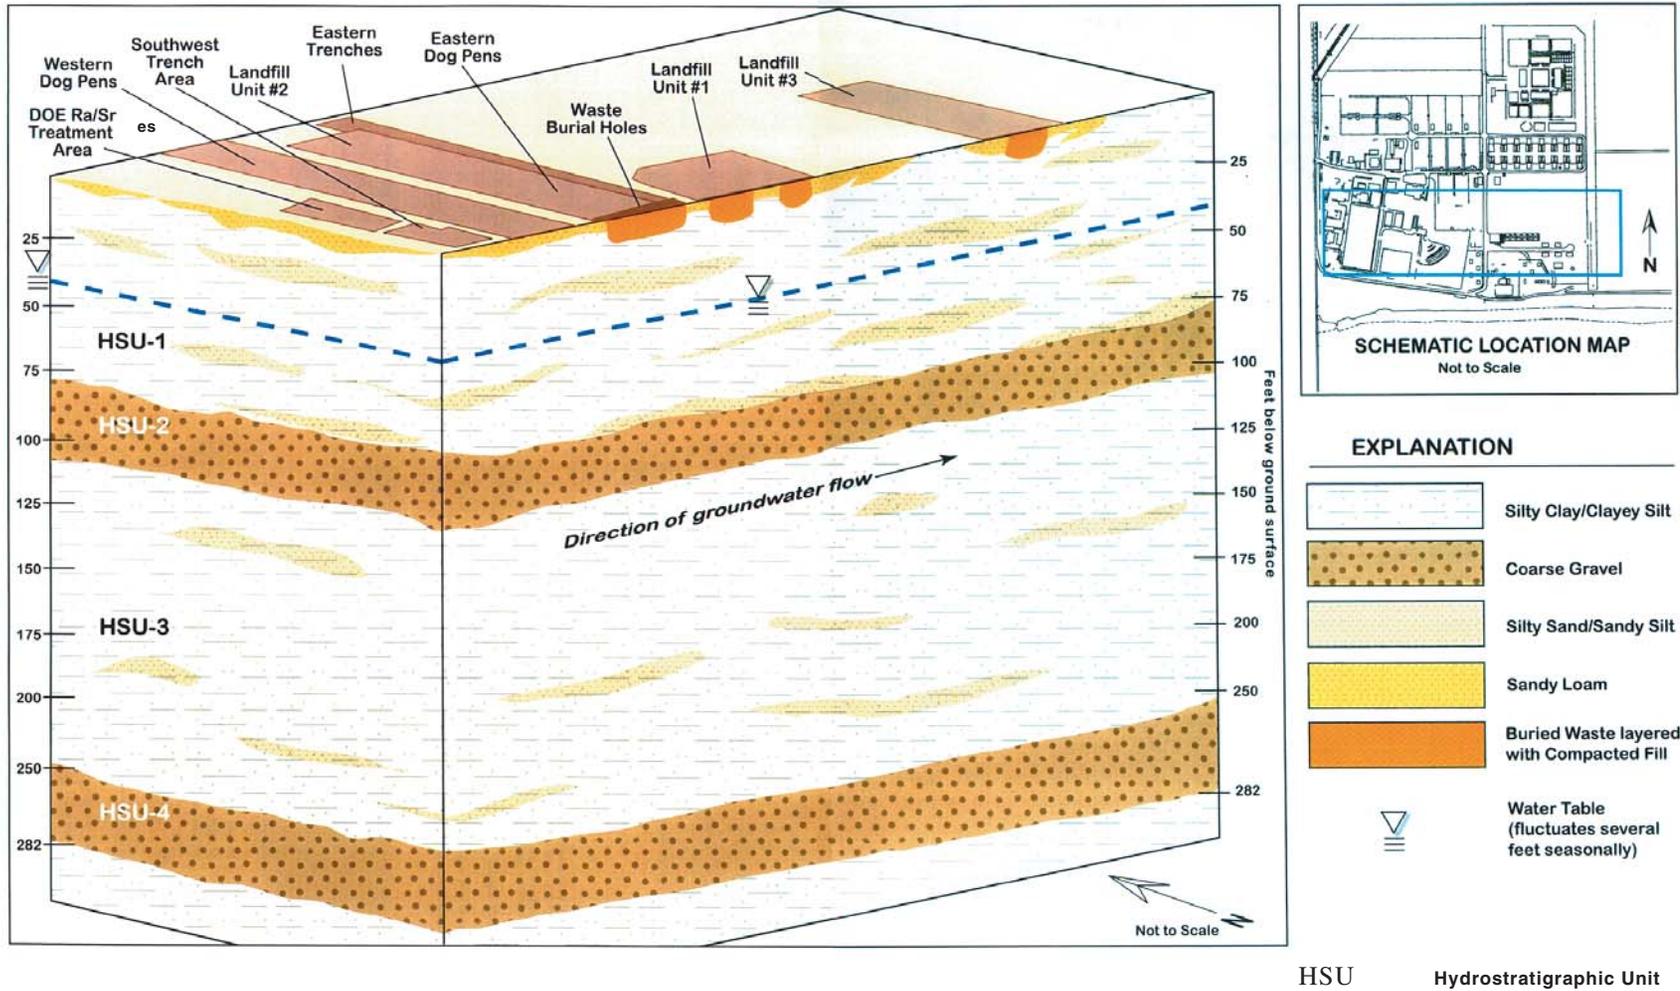

3.8.2 Wildlife

A variety of animal species have been observed at LEHR and the adjacent areas. Although many of these animal species are not likely to live at LEHR, they may forage there. Resident burrowing mammals observed at LEHR include the California ground squirrel, California vole, Botta's pocket gopher and various mice species. Common predatory mammals and reptiles likely to forage on-site include the coyote, gray fox, red fox, house cat, gopher snake and garter snake. Common predatory birds likely to forage on-site include the red-tailed hawk, red-shouldered hawk,

American kestrel, great-horned owl and barn owl. Common fish expected in the creek include largemouth bass, green sunfish, carp and catfish. Fish-eating animals likely to occur in the South Fork of Putah Creek include river otter, beaver and muskrat.

A total of seven special-status wildlife species are considered to have a moderate to high potential to inhabit or forage on-site. A total of 26 special-status wildlife species have been recorded in the vicinity of LEHR or are considered to have a moderate to high potential for occurrence in the area. A potential habitat for the valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) consisting of seven elderberry bushes was identified in both the WDPs and EDPs.

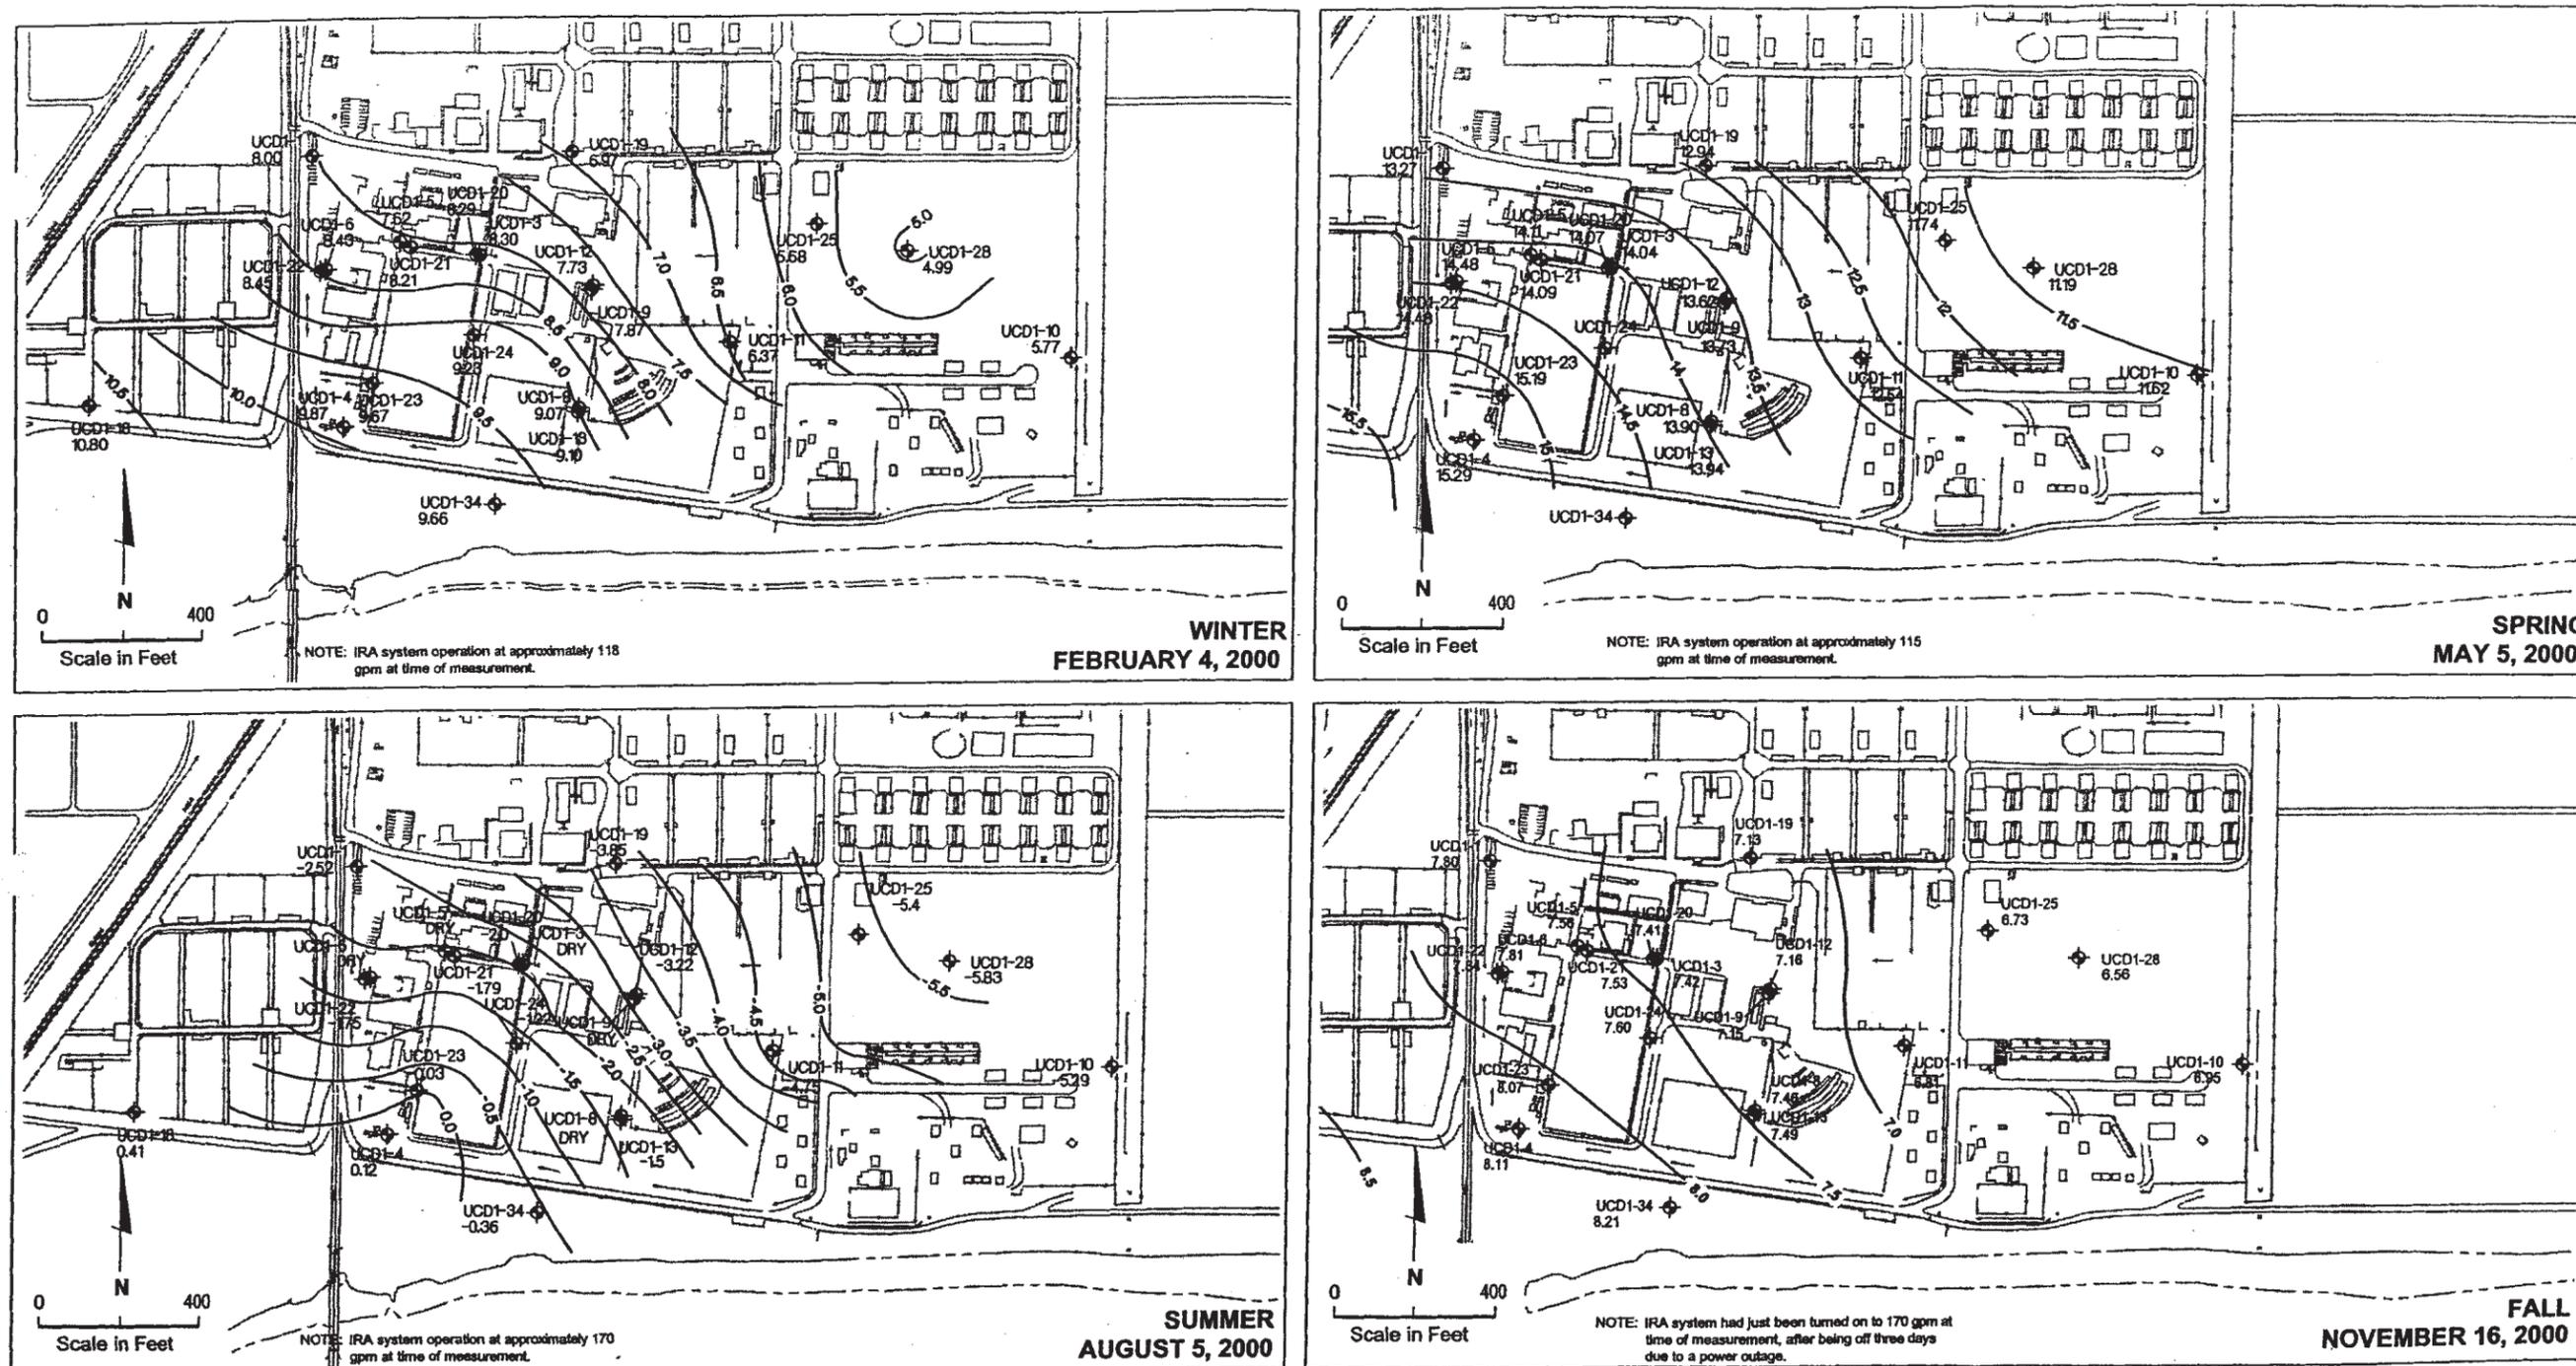

The South Fork of Putah Creek is identified as wetlands by the United States Army Corps of Engineers. Wetlands perform vital ecological functions and are important to the public interest. They provide communities with a variety of resident and migratory animal species habitat, breeding, spawning and forage areas. The dense vegetation and trees at the South Fork of Putah Creek channel represent an open space area that provides habitat for birds and small wildlife. Wetlands also provide for the movement of water and sediments, ground water recharge, water purification, storage of storm water runoff and recreation.

4. SITE BACKGROUND CONCENTRATIONS, CONTAMINANT FATE AND TRANSPORT, AND PRELIMINARY RISK SCREENING

This section describes the approach and procedures DOE has used as the basis for developing RBASs to guide the LEHR Federal Facility RAs. The basic elements of the DOE approach are: 1) establish background levels for naturally-occurring COCs (Figure 2-2); 2) develop RBASs for three selected scenarios for each COC; 3) designate the higher of background or the lowest RBAS as the RAS for each COC; and, 4) conduct a DL analysis for those COCs remaining after each RA that might potentially impact underlying ground water. Section 4.1 describes how the background COC levels in Table 4-1 were calculated. Section 4.3 describes RBAS development. Before RBASs could be calculated, COC fate and transport was evaluated, potential exposure pathways assessed, and likely exposure scenarios were developed. The fate and transport evaluation for RBAS development is summarized in Section 4.3.1 and exposure pathway and scenario development is summarized in Section 4.3.2. Section 4.3.3 summarizes the parameters and approach used for RBAS risk calculations for the three selected scenarios. Table 4-1 summarizes the results of these RBAS calculations. Section 4.4 summarizes the DL approach used to assess the likelihood of ground water impact from the COCs remaining in soil after each RA.

For the SWRA, UC Davis, with input from DOE, will evaluate the site-wide risk associated with both DOE and UC Davis contaminant sources based on data of adequate quality and representative of current site conditions. Although future risk assessment will replace them, the RBASs provide a useful reference for results presented in this RI. US EPA Region 9's preliminary remediation goals (PRGs) for soil under both the residential and industrial scenarios are included on Table 4-1 for comparison with the LEHR Federal Facility RBASs and are also used as references for results presented in this RI.

4.1 Site Background Concentrations

As discussed in Section 2.3.1, five field investigations have been conducted at and near the LEHR Site to obtain data for estimating background concentrations of naturally occurring constituents. A statistical testing approach was developed to analyze the data from these investigations, first to determine if constituents were stratified laterally, with depth and/or soil type, and then to establish background concentrations. This analysis is presented in detail in Appendix D of the RA Work Plan (WA, 2000c).

Based on the statistical analysis, nine of 19 metals and 12 of 21 radionuclides showed enough natural variability with depth to warrant calculation of two different soil background levels: one for 0 to 4 ft bgs, and one for greater than 4 ft bgs. To some extent this stratification with depth is related to

soil type (generally sandier in the first four ft). The statistical analysis found no significant lateral variation in soil background levels in samples collected in all directions from the LEHR Site.

After the appropriate data sets were identified, background levels were calculated for each constituent and depth interval. First the data distribution for each background constituent was examined to determine if it was normal, log-normal, or neither. Then the 80% lower confidence limit (LCL) on the 95th percentile of each data set was calculated based on the data distribution to establish the background level. For constituents with many concentrations below the detection limits, the maximum likelihood estimator procedure was used to calculate the 80% LCL on the 95th percentile (Gilbert, 1987). The background concentrations for LEHR Federal Facility COCs calculated using this approach are shown on Table 4-1.

4.2 Constituent of Concern Identification

To select the Site COCs, all of the chemical and radiological data collected at the Site were evaluated to determine if sample collection and analysis methods, quality assurance/quality control (QA/QC) procedures and database files were acceptable. Data that were not collected from DOE areas were excluded. Soil sample data were sorted by operable unit (OU) and chemical. All chemicals with no detections in soil were evaluated through historical records and data from other media to determine whether the compound was likely to be present. A background comparison was conducted to eliminate contaminants present below site-specific background. If less than ten¹ samples contained detectable concentrations, the maximum detected concentration was selected for comparison with background. Otherwise, the 95% upper confidence limit on the mean was calculated using US EPA procedures (US EPA, 1994b) for comparison with background.

Some compounds were below laboratory detection limits for all soil samples collected from the DOE areas. Compounds that were not detected in soil in any of the DOE areas, and were not believed to exist at the Site from review of previous site activities, were eliminated from the data set and were not included as potential COCs. For radionuclides, the entire data set, including concentrations reported below the sample-specific Minimum Detectable Activity (MDA) was used to calculate the concentration terms for comparison with background following DOE guidance (DOE, 1991).

Compounds that were detected in soil in any of the DOE areas were selected as potential COCs in ground water-related pathways. VOCs detected in soil in any of the DOE areas were selected as COCs in indoor and outdoor air for Scenario 1. VOCs were not considered COCs for Scenarios 2 and 3 (excluding the ground water pathway in Scenario 2) because contaminant transport is through fugitive dust dispersion and deposition. VOCs are not capable of remaining adsorbed to

¹ Sampling data from Superfund sites have shown that data sets with fewer than 10 samples per exposure area provide poor estimates of the mean concentration (US EPA, 1992). Thus, the maximum concentration is selected to represent the data set.

fugitive dust particulates during dispersion and deposition transport process due to rapid volatilization.

All compounds except VOCs in soil in the DOE areas were selected as COCs in fugitive dust emissions and soil deposited after off-site transport to receptor locations in Scenarios 2 and 3. Non-volatile contaminants present in fugitive dust, and therefore possibly present in off-site soil as a function of deposition, were also selected as COCs in milk, meat and fruit/vegetable media due to possible contaminant uptake for Scenarios 2 and 3.

Compounds that were detected in both DOE OU soil and storm water runoff were selected as COCs in storm water. The method detection limit (MDL) was compared to US EPA fresh water ambient water quality criteria or California Inland Surface Water criteria for compounds that were detected in soil but not detected in storm water run off. If the MDL was above ambient water quality criteria the compound was selected as a potential COC in surface water.

4.3 Risk-Based Action Standard Development

DOE developed RBASs for soil potentially impacted by the LEHR Federal Facility primarily to provide guidelines for non-time-critical RAs. As described in Section 6.1, the first two removal action objectives (RAOs) for each RA were: 1) reduce the cumulative cancer risk to a nominal range of 10^{-4} to 10^{-6} , using 10^{-6} as the point of departure; and, 2) reduce the cumulative non-cancer HQ to below 1.0. The RBAS for individual COCs were used to calculate these risks.

The approach for establishing RBASs for LEHR Federal Facility soil was agreed to by the RPMs in 1997 and is summarized in Figure 4-1. First, chemical and radionuclide COCs were identified as those present in soil above background levels. Next, RBASs for these contaminants were calculated using the Argonne National Laboratory computer model RESRAD (Residual Radioactivity [model]) for radionuclides and a RAGS-based approach for chemical constituents. To complete the RESRAD back-calculations, it was necessary to relate LEHR Federal Facility source area soil concentrations to concentrations in exposure media at the receptor location for selected scenarios. This required: 1) developing likely exposure scenarios based on the site conceptual model; and 2) conducting fate and transport modeling to establish the relationship between source area COC levels and those in the exposure media at the receptor location for each scenario. This process is described further in the following subsections.

4.3.1 Fate and Transport Evaluation

Fate and transport modeling was conducted to correlate LEHR Federal Facility source area concentrations to those in exposure media at the receptor locations for each of the three scenarios developed for RBAS calculation (Sections 4.3.2 and 4.3.3). Detailed descriptions of the modeling approaches, parameters and results are included in Attachments C through G of the *Draft Final Determination of Risk-Based Action Standards for DOE Areas* (WA, 1997d). In summary,

contaminant fate and transport in air, soil, surface water, ground water, and biological media were modeled using RAGS or other US EPA-recommended models when available, and RESRAD was used for radionuclides. As discussed in more detail in Section 4.4, the NUFT model (Nitao, 1998) was used to evaluate transport from the vadose zone to ground water. The use of this model is discussed in the RPM-approved *Work Plan for Removal Actions in the Southwest Trenches, Ra/Sr Treatment Systems, and Domestic Septic System Areas* (WA, 2000c).

Site physical characteristics such as precipitation, surface runoff, wind direction/speed, subsurface hydrogeology, and Putah Creek flow used in the fate and transport modeling are discussed in Section 3. For RBAS calculations, the subsurface geology was generalized and COCs were conservatively assumed to be uniformly distributed in the first 15 ft of the subsurface. As discussed in Section 4.4, these assumptions were modified for the post-RA DL analysis based on area-specific information. In addition, area-specific Hg RBASs were calculated for the SWT and WDPs areas. Calculation of area-specific Hg RBASs for the Ra/Sr Treatment Systems is in progress.

4.3.2 Exposure Pathways and Scenarios

Three exposure scenarios were considered based on the likely exposure pathways for LEHR and vicinity. Scenario 1, On-site Researcher, represented potential on-site workers that might be exposed to source area soil through external radiation from ground surface radionuclides (for radionuclides only), ingestion, inhalation and dermal exposure. Scenario 2, the East Side Residential Farmer, represents potential off-site residential farmers that might be exposed to potentially impacted ground and surface water (via recreational use), and via external radiation from ground surface radionuclides (for radionuclides only), inhalation of fugitive dust, soil ingestion, and agricultural foods potentially impacted by fugitive dust migration from the on-site source areas. Scenario 3, the South Side Residential Farmer, is identical to Scenario 2 except that exposure to impacted ground water was not included, since ground water flow is generally toward the east, away from this receptor location, and ground water contamination (if any) does not impact Putah Creek.

4.3.3 Risk Calculation

For chemical constituents, chemical dose, or intake, was calculated using the intake equations presented in *Risk Assessment Guidance for Superfund, Volume 1, Human Health Evaluation Manual (Part A)* (US EPA, 1989). Incremental human health risk was then calculated using toxicological parameters from the *US EPA Region IX August 1996 Preliminary Remedial Goals* tabulation and the US EPA's *Integrated Risk Information System* online database. RBASs for carcinogenic compounds were calculated for 10^{-4} , 10^{-5} , and 10^{-6} risk, consistent with NCP, 40 CFR part 300. RBASs for non-carcinogens were based on a HQ of 1.0, consistent with US EPA guidance. The RAS for source soil was then determined by iterative back-calculation to determine the source soil concentration that yields the target incremental cancer risk (or target HQ) value. The target incremental cancer risk (or target HQ) is a sum of risk (or HQ) across all pathways for a particular chemical and a particular exposure scenario. Radionuclide action standards were similarly calculated using RESRAD Version

5.62, which uses the US EPA dose conversion factors from the 1995 Health Effects Assessment Summary Tables (HEAST). For each radionuclide, the target risk is equivalent to a specific radiologic dose to the receptor. For chemical and radiological constituents, this approach closely parallels that devised in *Risk Assessment Guidance for Superfund, Part B, Development of Risk-Based Preliminary Remediation Goals* (US EPA, 1991), in which soil concentrations equivalent to RBASs are back-calculated based on a target risk level, rather than a forward calculation approach in which measured concentrations in environmental media are used to estimate risk.

Table 4-1 presents the RBASs calculated for a 10^{-6} incremental cancer risk and/or HQ of 1.0 for each of the three scenarios for all LEHR Federal Facility COCs. Site-specific background levels are also presented. Note that the RBASs for inorganic chemicals are especially conservative because they include the risk associated with background levels. In the event that the calculated RBAS was below the site-specific background level for a given contaminant, the RAS used during the RAs was the site-specific background level. On Table 4-1, the RAS for each COC is shown in bold-type, and the US EPA PRGs for residential and industrial scenario soil are included for comparison. As shown on Table 4-1, the lowest RBAS is typically within an order of magnitude of the residential PRG. For most of the key LEHR Federal Facility COCs, including Ra-226, Sr-90, chlordane, and Hg, the site-specific RAS is lower than the residential PRG.

As noted above, the RBASs have been used to guide the LEHR Federal Facility RAs. In addition, the RBAS assumptions and calculations have been used for forward risk calculations following the RAs. The cumulative cancer risk and non-cancer hazard resulting from all COCs remaining following each RA were calculated, and in every case were found to be at the lower end of the 10^{-4} to 10^{-6} excess cancer risk range and below a cumulative non-cancer HQ of 1.0, indicating the RAOs were achieved.

4.3.4 Risk Assessment Exposure Pathways and Scenarios

The exposure pathways for potential receptors used in the upcoming Site-Wide Risk Assessment are described below. This information was taken directly from the *Draft Site-Wide Risk Assessment* (UCD, 2003). Figures 4-2 through 4-4 show the potentially complete exposure pathways for all of the DOE areas. The exposure pathways for the potential ecological receptors are discussed in the *Draft Tier 1 Ecological Risk Assessment* (UCD, 2002c).

4.3.5 The On-Site Outdoor Researcher

- Air—An on-site outdoor researcher might inhale dust containing Site-related chemicals migrating from surface soil. Though waste buried on-site was reported to be covered with non-impacted soil, adequate data has not been collected to eliminate this pathway.

- Soil—With the same caveat, an on-site outdoor researcher might ingest and dermally contact surface soil in the course of his/her day. In addition, an on-site outdoor researcher might inhale VOCs migrating from subsurface soil.
- HSU-1 Ground water—An on-site construction worker might inhale VOCs migrating from HSU-1 ground water.

The UC Davis water supply is drawn from deep ground water campus wells (300-700 ft bgs) upgradient of the site, so ingestion and dermal exposure to Site ground water was excluded as a pathway.

4.3.6 *The On-Site Indoor Researcher*

An on-site indoor researcher could be exposed to Site-related chemicals through the following media and exposure routes:

- Air—An on-site indoor researcher might inhale dust containing Site-related chemicals migrating from surface soil (but less than an outdoor researcher). Again, no surface soil contamination is known to currently exist.
- Soil—An on-site indoor researcher might ingest and dermally contact surface soil in the course of his day (but less than an outdoor researcher). In addition, an on-site indoor researcher might inhale VOCs migrating from subsurface soil and ground water and into the building.

The UC Davis water supply is drawn from deep campus wells (300-700 ft bgs) upgradient of the site, so ingestion and dermal exposure to Site ground water was excluded as a pathway for the on-site indoor researcher.

4.3.7 *The On-Site Construction Worker*

An on-site construction worker could be exposed to Site-related chemicals through the following media and exposure routes:

- Air—An on-site construction worker might be exposed to external radiation from soil or inhale dust containing Site-related chemicals migrating from surface soil (see caveat above).
- Soil—An on-site construction worker might ingest and dermally contact both surface and subsurface soil. In addition, an on-site construction worker might inhale VOCs migrating from subsurface soil.
- HSU-1 Ground water—An on-site construction worker might inhale VOCs migrating from HSU-1 ground water.

A construction worker would only be exposed to site-related chemicals for the duration of construction work on-site. The UC Davis water supply is drawn from deep campus wells (300-700 ft bgs) upgradient of the site, so ingestion and dermal exposure to Site ground water was excluded as a pathway. The HSU-2 and HSU-4 aquifers are too deep for exposure during construction activities.

4.3.8 *The Hypothetical On-Site Resident*

A hypothetical on-site resident could be exposed to Site-related chemicals under two scenarios including UC Davis development of residential housing, and by UC Davis selling the property to an owner who develops the Site as a residential property. The following media and exposure routes will be considered for the hypothetical on-site resident:

- Air—A hypothetical on-site resident might inhale dust containing Site-related chemicals migrating from surface soil. In addition, a hypothetical on-site resident might eat fruits and vegetables that have wind-deposited chemicals upon them.
- Soil—A hypothetical on-site resident might be exposed to radiation or ingest or come in dermal contact with surfaced soil. A hypothetical on-site resident might also eat fruits and vegetables grown on this soil. In addition, a hypothetical on-site resident might inhale VOCs migrating from subsurface soil and into a house.
- HSU-1 Ground water—A hypothetical on-site resident might inhale VOCs migrating from HSU-1 ground water and into a house.
- HSU-2 Ground water—A hypothetical on-site resident might place a well in HSU-2 and use it for drinking (ingestion) and household use (inhalation). (This is unlikely in the case of UC Davis residential housing, since UC Davis supplies water to all on-site residents from wells approximately 1,500 ft bgs).
- HSU-4 Ground Water—A hypothetical on-site resident might place a well in HSU-4 and use it for drinking (ingestion) and household use (inhalation). (This is unlikely in the case of UC Davis residential housing, since UC Davis supplies water to all on-site residents from wells approximately 1,500 ft bgs).
- Surface water and sediment—A hypothetical on-site resident might swim and fish in Putah Creek. A hypothetical on-site resident might also eat fish caught in the creek.

HSU-1 is composed of predominantly fined grained silts and clays. Wells completed within HSU-1 have very low flow rates (1 to 5 gpm, often going dry in the summer) and would not support a water supply well. Section 3.2.1 discusses of site hydrogeologic conditions, including details of HSU-1. Based on its hydrogeologic properties, HSU-1 was not included for an ingestion and dermal contact scenario in this report.

Although HSU-1 is not used for domestic purposes and is unlikely to support a future sustainable water supply well, it meets the Central Valley Regional Water Quality Control Board Basin Plan standards as a potential potable water unit. As such, residential use scenarios, which include an analysis of risk posed by ingestion and dermal contact from HSU-1 ground water, should be performed by UC Davis in the Site-Wide Risk Assessment.

4.3.9 *The Off-Site Farm Resident (East)*

Hypothetically, an off-site farm resident (east) could be exposed to Site-related chemicals through the following media and exposure routes:

- Lateral transport in HSU-1 is limited, therefore, exposure to HSU-1 ground water was not considered for the off-site farm resident.
- HSU-2 Ground water—An off-site resident living to the east of the Site might place a well in HSU-2 and use it for drinking (ingestion) and household use (inhalation).
- HSU-4 Ground water—An off-site resident living to the east of the Site might place a well in HSU-4 and use it for drinking (ingestion) and household use (inhalation).
- Surface water and Sediment—An off-site resident living to the east might swim and fish in Putah Creek. An off-site resident might also eat fish caught in the creek.

4.3.10 *The Off-Site Farm Resident (South)*

Conceptually, an off-site farm resident (south) could be exposed to Site-related chemicals through the following media and exposure routes:

- Air—For purposed of the CSM, an off-site resident might inhale wind-blown chemicals from the Site.
- Surface Soil—An off-site resident might ingest or come in dermal contact with chemicals blown onto his farm's surface soil by the wind.
- Surface Water and Sediment—An off-site resident living to the south might swim and fish in Putah Creek. An off-site resident might also eat fish caught in the creek.

Ground water was not considered an exposure medium for this receptor because ground water does not flow south.

4.4 Designated-Level Analysis

In addition to reducing cancer risk and non-cancer hazards below acceptable levels as described in Section 4.3, another key RAO for LEHR Federal Facility RAs was to mitigate any potential future impacts to ground water (Section 6.1). DL analyses were conducted to determine whether this objective had been attained. The same vadose zone transport model used in developing the RBASs was also used for DL analyses, but without considering attenuation away from the source and with these site-specific modifications: 1) focused on source area-specific, post-RA COCs only; 2) used source area-specific, post-RA soil profile and contaminant distribution; 3) used the US EPA and California (whichever is lower) MCL and background levels as the ground water criteria instead of risk-based values.

The DL analysis is a screening tool to evaluate if contaminants in soil pose a risk to ground water. However, as with any one dimensional model simulating a complex three-dimensional system, the DL modeling may significantly underestimate or overestimate contaminant transport. The assumptions and parameters used in the modeling were generally conservative and may overestimate transport. However, the model cannot consider macropores (fractures) or other three dimensional heterogeneities that might provide a direct pathway between the ground surface and the ground water, and therefore the model may underestimate transport. No macropores have been observed during subsurface characterization at the LEHR site.

The DL analysis approach used for the LEHR Federal Facility source areas is described in detail in the RPM-approved *Work Plan for Removal Actions in the Southwest Trenches, Ra/Sr Treatment Systems, and Domestic Septic System Areas* (WA, 2000c) and the *Southwest Trenches Area Removal Action Confirmation Report* (WA, 2001e). The approach consisted of three phases. Phase A, Preliminary DL Analysis, involved screening the RA confirmation data and all validated data with accurate x and y coordinates for sample locations through a series of steps to arrive at a list of "DL COCs". The Phase A DL analyses for the Ra/Sr Treatment Systems and SWT areas were re-run with valid investigation data representing current site conditions. The Phase A DL analysis summary tables are presented in Appendix H. The results of additional DL modeling conducted for the Ra/Sr Treatment Systems and SWT areas are discussed in Section 6. The screening steps included comparison with background levels and consideration of half-lives, biodegradability, and adsorption coefficients (K_d), in addition to previous vadose zone modeling results. Once the DL COC list was established, Phase B, Data Gaps Investigation, was conducted, if necessary, to collect additional vertical profile data on the DL COC.

Phase C, Refined DL Analysis, entailed conducting vadose zone modeling and comparing the resultant ground water-protective soil concentrations to the actual soil concentrations remaining in that source area. The details of the model, including the selection of input parameter values and model setup, are presented in the *Draft Final One-Dimensional Vadose Zone Modeling for the U.S. DOE Areas at LEHR* (WA, 1997b). Appendix G includes tables that summarize the NUFT model input parameters and results of modeling conducted for the DOE Areas. Source area-specific modifications and results are described in the *Ra/Sr Treatment Systems and SWT Area RA Confirmation Reports* (WA, 2001c and 2001e) and the *Dog Pens Engineering Evaluation/Cost Analysis* (EE/CA) (WA, 2001a), and are summarized by source area in Section 6. Comparison of DL

results to observed ground water contamination is also summarized by source area in Section 6. COC concentrations in ground water from wells within or immediately downgradient of the source area were compared to background ground water concentrations. Background COC concentrations were defined as the 80th LCL of the 95th percentile (or half the detection limit for constituents that were not detected) for ground water data from upgradient well UCD1-18 (Figure 2-3).

Notes

Scenario 1 - On-Site Researcher, Scenario 2 - East-Side Residential Farmer, and Scenario 3 - South-Side Residential Farmer

Screening criterion (higher of lowest RBAS and background) for each constituent is shown in **bold type**.

PRGs lower than screening criteria are shown in *italics*.

¹ Background concentration calculations are presented in Appendix C of WA, 2000c.

² Chemical PRGs are from US EPA Region 9 PRGs Table, dated February, 2003. Radionuclide PRGs are from Radionuclide Toxicity and PRGs for Superfund, dated April 14,2003 (US EPA, http://epa-prgs.ornl.gov/radionuclides/download/rad_master_prg_table_pci.xls). The industrial PRGs for radionuclides are for "outdoor worker soil." California modified PRGs are shown in brackets.

³ Total chlordane

⁴ Risk not exceeded for free-phase interstitial compound. Assumes 10% by weight (i.e., 100,000 mg/kg) as the maximum soil concentration.

⁵ Lowest RBAS is based on non-carcinogenic effects.

⁶ First number is for samples collected 0 to 4 ft bgs, second is for >4 ft bgs.

⁷ First number is for soil from 0 to 4 ft bgs, second is for >4 ft bgs.

⁸ Shallow soil mercury background not used as action standard because of potential analytic problems.

⁹ RBAS recalculated for each removal action using area-specific lithology and mercury distribution data and site-specific mercury species data.

¹⁰ Mercury and compounds.

¹¹ Only applies to RBAS.

5. DATA QUALITY EVALUATION

5.1 Data Usability Approach

LEHR Federal Facility data quality was evaluated to determine whether the data were usable to support the findings, conclusions, and recommendations presented in this RI. Data can be classified into one of two general categories: 1) those collected as part of the RI; and, 2) non-RI data. RI data were collected to CERCLA standards and have been validated to US EPA Contract Laboratory Program (CLP) standards. Non-RI data were either collected prior to LEHR site NPL listing in 1994, or were collected for a reason other than Site characterization (e.g., for health and safety or waste management purposes). These data were either not collected to CERCLA standards or were not validated, or no documentation regarding collection methods and/or validation is available.

In general, non-RI data were used qualitatively to guide subsequent RI investigations. All valid RI data have been used to quantitatively define the nature and extent of contamination at the Site. Table 5-1 lists each investigation conducted at the LEHR Federal Facility, the level of data quality for that investigation, and specific information regarding how that data set was used in the RI.

5.2 Remedial Investigation Data Usability

Data management, validation procedures, and data assessment for all LEHR Federal Facility RI soil, air, storm water, and ground water data are presented in detail in Appendix A and summarized in the following sections.

5.2.1 Data Management

Data management is a coordinated effort between the Project Chemist and Database Manager. The Project Chemist manages each sample from collection to final data package archiving and the Database Manager is responsible for all data from receipt of the electronic data deliverable (EDD) to final import into the permanent database.

The Project Chemist records and tracks the progress of each sample and manages validation of the data. When data validation is complete the Project Chemist notifies the Database Manager that the data are ready for the electronic import process. The Project Chemist or a qualified designee compares the electronic copy to the laboratory hard copy, makes any necessary corrections to the

copies, and enters the qualifiers from the data validation process. The Project Chemist approves the data for import and the Database Manager imports the data into the permanent database table.

Location data from professional surveys and sample location data collected by field personnel are transferred to electronic form and imported into the database table by the Database Manager or a qualified designee. Data integration or exchange between DOE and UC Davis was conducted in accordance with the *Final Data Integration Strategy Memorandum* (WA, 2000e).

5.2.2 Data Validation and Review Pursuant to Data Quality Objectives

Data review or full data validation was performed on 100% of the samples using the guidance of the US EPA *Contract Laboratory Program National Functional Guidelines for Organic Data Review* (US EPA, 1998a) and *US EPA Contract Laboratory Program National Functional Guidelines for Inorganic Data Review* (US EPA, 1998b). Data validation and review were conducted in accordance with Section 9 of the *Final Quality Assurance Project Plan* (Weiss, 2000d). Full data validation was performed on 10% of site investigation and confirmation samples, and data review was performed on the remaining 90%. Organic data were reviewed for holding times, blank analysis results, gas chromatograph/mass spectrometer tuning, instrument calibrations, internal standard areas, laboratory control samples, matrix spike/matrix spike duplicate, and surrogate recovery. Metals, general chemistry and radiochemistry data were reviewed for holding times, blank analysis results, matrix spike/matrix spike duplicate /sample duplicates, laboratory control samples, and instrument calibrations.

The sampling and analysis programs that were conducted during the CERCLA investigations and RAs were developed using the data quality objectives (DQOs) process described in Guidance for the Data Quality Objectives Process, US EPA document number QA/G-4 EPA/600/R-96/055 (US EPA, 2000). The DQO process is a systematic planning tool for establishing criteria for DQOs and for developing data collection designs. The seven steps used to design the sampling and analysis programs are: 1) statement of the problem; 2) identification of decisions; 3) identification of inputs to decisions; 4) definition of study boundaries; 5) development of decision rules; 6) specification of limits on decision errors; and, 7) sample design optimization.

5.2.3 Data Assessment

The data assessed for use in the RI are laboratory results collected to characterize the current condition of the DOE RI Areas at the LEHR Site. The laboratory results apply to:

- All soil or solid samples used for site characterization or RA confirmation in DOE RI Areas that were collected to CERCLA standards after the site was listed on the NPL.
- Ground water samples from wells UCD1-4, UCD1-12, UCD1-13, UCD1-18, UCD1-20, UCD1-21, UCD1-23, and UCD1-24 (UC Davis wells used to assess

potential ground water impact from DOE areas) and all storm water monitoring samples collected from 1995 through 2001.

- All air monitoring samples.

This data assessment identified all qualified and unqualified data and evaluated the impact of qualified data on use in the RI (see Appendix A). In general, the impact from qualified data was insignificant and did not affect the findings, conclusions, and recommendations made in the RI. A summary of the percentage of qualified and unqualified data and the qualifier definitions are presented below in Table 5-2.

Table 5-2. Percentages of Qualified and Unqualified Data

Sample Type	R Qualified	J Qualified	UJ Qualified	Not-Detected U Qualified	Unqualified Detection
Soil	0.3%	5 %	8 %	69%	83%
Water	0.1 %	2 %	6 %	80 %	90 %
Air	0.1 %	5 %	10 %	60 %	90 %

- R Qualified—Sample results are rejected with an "R" qualifier when a data validation expert reviews the laboratory data and finds evidence of serious deficiencies in the ability to analyze a sample and meet QC criteria. The "R" qualifier indicates that the data cannot be used to verify whether the analyte was present or absent from the sample. "R" qualified results were not used in the RI.
- J Qualified—Application of the J qualifier to analytical data means that the analyte was positively identified in the sample, but the analytical result is an approximation of the analyte concentration in the sample. These data were used qualitatively in the RI.
- UJ Qualified—Application of the UJ qualifier means the analyte was not detected above the reported quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. The quantitation limit is greater than the detection limit and it represents the lowest level that the concentration value is accurate and precise. These data were used qualitatively in the RI.
- U Qualified—Application of the U qualifier means the laboratory analyzed for the analyte, but the analyte was not detected above the reported sample detection limit (non-detect results). These data were used quantitatively in the RI.
- Unqualified Detection—These data were detected in the sample and found to be accurate and precise by the data validation expert. These data were used quantitatively in the RI.

The only DOE Areas data used in the RI whose data quality was significantly impacted were several Cr-VI results qualified "UJ" due to laboratory contamination. The laboratory contamination for these qualified results was significant in comparison to the RA and ground water protection standards. The qualified Cr-VI results are shown in Table A-6 and the impact on data quality is discussed in Appendix A.

The percentages of DOE Areas data that were qualified due to hexavalent chromium blank contamination are:

Southwest Trenches Area – 16%

Domestic Septic System 4 – 50%

Dry Wells Area – 20%

Radium/Strontium Treatment Systems Area – 9%

Western Dog Pens – 25%

The percentage of hexavalent chromium contaminated soil blanks for all DOE Areas data was 14% of soil blanks analyzed. This percentage is significant enough to cause DOE areas to fail the sensitive statistical tests used to evaluate cleanup attainment and could result in a decision to initiate cleanup in areas that have attained background concentrations. Because of the blank contamination, these data were only used qualitatively in the RI with the knowledge that they carried a positive bias near or above the RA and ground water protection standards.

The positive bias in hexavalent chromium data for DOE Areas soil samples was compounded by a negative bias in hexavalent chromium results for background soil samples collected in 1997. The two forms of bias are a compounded problem because background is a primary point of comparison for DOE Areas data. All of the hexavalent chromium results for background soil samples collected in 1997 were qualified due to matrix spike recoveries below control limits, which indicates the negative bias. The hexavalent chromium background value of 0.054 milligrams per kilogram (mg/kg) carries this bias because it was determined using only 1997 background data.

The negative bias in hexavalent chromium soil background was likely due to the sample preparation method used by the laboratory. The background soil samples were prepared following California Air Resources Board (CARB) Method 425, which was designed for air samples rather than soil matrices. Subsequent samples were prepared following EPA Method 3060A, which was designed for soil matrices.

5.3 Changes/Improvements in Methodology

The quality of laboratory data has changed for several analytes during the LEHR project due to changes in analytical methods and contract laboratories. The changes have resulted in improved analytical precision, accuracy, sensitivity, and qualitative identification of analytes. Data validation

qualifiers do not necessarily reflect these changes because data are validated independently and not comparatively.

The most notable improvement in data quality resulted from changes made to the Ra-226 analytical method at the recommendation of California Department of Health Services. Beginning in October 1997, the Ra-226 analytical method was improved by employing a daughter product in-growth technique. The daughter products Lead-214 (Pb-214) and Bismuth-214 (Bi-214) were allowed a 30-day in-growth period before counting and determining Ra-226 based on decay chain equilibrium. Ra-226 was previously analyzed by alpha spectroscopy using modified EPA Method 903.1 and direct gamma spectroscopy using modified EPA Method 901.1, which were less precise and had poor sensitivity. The direct gamma spectroscopy method was especially problematic because it relied on the 186 kilo-electron volt (keV) Ra-226 gamma spectra, which is poorly resolvable due to U-235 interference at the same energy. Ra-226 data presented in this RI include alpha spectroscopy results prior to October 1997 and in-growth gamma spectroscopy after that date. Gamma spectroscopy results using the 186 keV Ra-226 spectra were not used.

Improvements in the Sr-90 sample preparation method were also implemented in October 1997. Samples were previously prepared using a selective purification process to form strontium carbonate precipitate, which was counted for gross beta by EPA Method 905.0. Because the precipitation process occasionally failed to selectively separate strontium in the sample, the Sr-90 result sometimes greatly exceeded the sample's gross beta activity. After implementing a column separation technique to fractionate strontium from the sample, no Sr-90 results were found to significantly exceed the gross beta activity.

A statistically significant change in analytical method/procedure accuracy between November 1994 and October 1997 was found for six analytes when background soil boring data were analyzed. The findings of the background analysis are presented in Appendix C of the *Final Southwest Trenches Area 1998 Removal Action Confirmation Report* (WA, 2001e). The effected analytes were Pb, actinium-228, gross alpha, gross beta, Pb-214 and thorium-234 (Th-234). Because background soil data collected in November 1994 were found to have conclusively shifted sample means, the data were eliminated from background value determinations for the six analytes.

In general, data quality was improved or remained the same for all analytes due to the analytical method and procedure changes that were implemented in November 1997. None of the analytes showed a significant decline in method sensitivity or precision after the 1997 changes were implemented.

Updated CLP standards were implemented for inorganic and organic compound analytical methods. The inorganic method of metals analysis was updated from CLP inorganic laboratory method (ILM) 3.0 to CLP ILM 4.0 in June 2000. The analytical method for pesticides/PCBs, VOCs and SVOCs was updated from CLP organic laboratory method (OLM) 3.1 to CLP OLM 4.2 in April 2002. No significant changes in data quality were found with the CLP method updates.

Table 5-1. LEHR Federal Facility Data Set Usability

LEHR Federal Facility Data Set	Data Set Description ⁽¹⁾	Data Quality ⁽²⁾	Data Use for RI
1993 Background Soil Data	From boreholes for wells UCD2-17 and UCD1-18 (Table 2-1)	Not performed under CERCLA; no record of data validation	Qualitative comparison with subsequent background data
1994 Background Soil Investigation	24 samples from six, 39-ft borings (Table 2-1)	Data collected/validated to CERCLA standards; no significant quality issues	Developing statistically-based Site background levels ⁽³⁾
1997 Background Soil Investigation	52 samples from six, 40-ft borings (Table 2-1)	Data collected/validated to CERCLA standards; all 52 Cr-VI results were qualified for negative bias based on matrix spike recoveries below the established control limits; no other significant quality issues	Developing statistically-based Site background levels
1999 Background Soil Investigations	Surface and 2 ft bgs samples from 20 locations, plus five samples for mercury analysis only (Table 2-1)	Data collected/validated to CERCLA standards; no significant quality issues	Developing statistically-based Site background levels
1984-1992 Ra/Sr Area Soil Investigations	Approximately 100 samples from 27 borings, plus several samples of sludge/soil from within/beneath tanks (Table 6-2)	Not performed under CERCLA; no record of data validation	Qualitatively for developing COC list and designing subsequent investigations/RAs
1996 Ra/Sr Area Soil Investigations	75 samples from five trenches and five borings (Table 6-2)	Data collected/validated to CERCLA standards; no significant quality issues	Defining the pre-RA contaminant nature/extent and designing the RAs
1999-2000 Ra/Sr Area Confirmation Sampling	78 soil samples from excavation floor/sidewalls (Section 6.2.4)	Data collected/validated to CERCLA standards; 10 of 78 Cr-VI results (13%) were qualified to indicate positive bias due to laboratory contamination; no other significant quality issues	Defining the post-RA contaminant nature/extent

Table 5-1. LEHR Federal Facility Data Set Useability (continued)

LEHR Federal Facility Data Set	Data Set Description ⁽¹⁾	Data Quality ⁽²⁾	Data Use for RI
2001 Ra/Sr Area DL Sampling	69 soil samples from 13 borings, analyzed for C-14, Cs-137, Cr-VI, Hg, nitrate, or Ra-226 (Table 6-6)	Data collected/validated to CERCLA standards; no significant quality issues	Defining the post-RA contaminant nature/extent
1996-1998 Old Davis Road Sediment Sampling	18 shallow soil samples for COCs plus 47 shallow soil samples for Cs-137 only (Sections 6.2.2.2 and 6.8.3)	Data collected/validated to CERCLA standards; no significant quality issues	Evaluating the potential impact from Ra/Sr Treatment System overflows and other surface water runoff from the Site
1995 DSS 2 Sampling	Radionuclide analyses of several soil samples (Table 6-8)	Data collected/validated to CERCLA standards; no significant quality issues	Defining the pre-RA contaminant nature/extent and designing the Ra/Sr Area RAs
1996-1997 DSS Investigations	Several samples each from approximately 40 borings near DSS 1, 3, 4, 5 and 6, and from trenches near DSS 1 and 7 (Table 6-8)	Data collected/validated to CERCLA standards; no significant quality issues	Defining the contaminant nature/extent
2001 DSSI	Several samples from DSS 1, 3, 4, 5 and 6, and 25 samples from five borings near DSS1 and 5 leach field (Table 6-8)	Data collected/validated to CERCLA standards; 4 of 5 Cr-VI results from DSS 4 and 7 of 22 Cr-VI results from the dry wells were qualified to indicate positive bias due to laboratory contamination; no other significant quality issues	Defining the contaminant nature/extent and designing the DSS 3 and 6 RAs
2002 DSS 1/4/5 DL Sampling	Five soil samples plus one grab ground ⁽⁴⁾ water sample from one boring to approximately 30 ft bgs in each DSS area (Tables 6-10 and Appendix J)	Data collected/validated to CERCLA standards; no significant quality issues	Defining the contaminant nature/extent

Table 5-1. LEHR Federal Facility Data Set Useability (continued)

LEHR Federal Facility Data Set	Data Set Description ⁽¹⁾	Data Quality ⁽²⁾	Data Use for RI
2002 DSS 3 and 6 Confirmation and DL Sampling	Total of 54 confirmation samples and 28 samples from three DL borings to approximately 40 ft bgs (Tables 6-13, 6-14, 6-17, 6-18 and Appendix J)	Data collected/validated to CERCLA standards; no significant quality issues	Defining the post-RA contaminant nature/extent
1984-1990 WDP Investigations	Surface radiation surveys and approximately 50 soil samples from surface/near-surface and borings	Not performed under CERCLA; no record of data validation	Qualitatively for developing COC list and designing subsequent investigations
1994 WDP Soil Investigation	44 samples from 19 borings	Data collected/validated to CERCLA standards; no significant quality issues	Defining the pre-RA contaminant nature/extent and designing subsequent investigations
1996 WDP Soil Sampling	Surface radiation surveys and 24 soil samples from WDP and EDP	Conducted for worker health & safety purposes; not fully validated	Qualitatively for developing COC list and designing subsequent investigations/RA
1997-1998 WDP Soil/Gravel Investigations	Surface radiation surveys, 46 gravel, and 181 soil samples from surface/near-surface and 20 borings	Data collected/validated to CERCLA standards; Cr-VI results for 46 of 181 (25%) of the soil samples were qualified to indicate positive bias due to laboratory contamination; no other significant quality issues	Defining the pre-RA contaminant nature/extent and designing the RA
2001 WDP Confirmation Sampling	38 soil samples (Section 6.4.4)	Data collected/validated to CERCLA standards; Cr-VI results for 27 of 38 samples were qualified to indicate positive bias due to laboratory contamination; no other significant quality issues	Defining the post-RA contaminant nature/extent

Table 5-1. LEHR Federal Facility Data Set Useability (continued)

LEHR Federal Facility Data Set	Data Set Description ⁽¹⁾	Data Quality ⁽²⁾	Data Use for RI
1984-1990 EDP Investigations	Surface radiation survey and 16 samples from two, 10-ft borings	Not performed under CERCLA; no record of data validation	Qualitatively for developing COC list and designing subsequent investigation
1996 EDP Soil Sampling	Surface radiation surveys and 24 soil samples from EDP and WDP	Conducted for worker health & safety purposes; not fully validated	Qualitatively for developing COC list and designing subsequent investigation
1999 EDP Soil/Gravel Investigations	40 soil, 16 gravel, and six curb samples from surface/near-surface	Data collected/validated to CERCLA standards; no significant quality issues	Defining the contaminant nature/extent
1984-1992 SWT Investigations	Soil samples from total of 20 exploratory trenches and three borings	Not performed under CERCLA; no record of data validation	Qualitatively for developing COC list and designing subsequent investigations/RA
1994-1995 SWT Investigations	Geophysical/soil gas surveys with three soil samples from two follow-up borings	Data collected/validated to CERCLA standards; no significant quality issues	Defining the pre-RA contaminant nature/extent and designing the subsequent investigation/RA
1996 SWT Investigation	Surface radiation survey and 38 soil/waste samples from six trenches and three borings	Data collected/validated to CERCLA standards; no significant quality issues	Defining the pre-RA contaminant nature/extent and designing the RA
1998 SWT Confirmation Sampling	70 soil samples for full COC suite and 37 soil and 11 cobble samples for partial COC suite (Section 6.6.4)	Data collected/validated to CERCLA standards; Cr-VI results for 20 to 70 (29%) samples were qualified to indicate positive bias due to laboratory contamination; no other significant quality issues	Defining the post-RA contaminant nature/extent

Table 5-1. LEHR Federal Facility Data Set Useability (continued)

LEHR Federal Facility Data Set	Data Set Description ⁽¹⁾	Data Quality ⁽²⁾	Data Use for RI
1999 SWT DL Sampling	40 soil samples from 6 borings, analyzed for tritium, C-14, or Cs-137	Data collected/validated to CERCLA standards; no significant quality issues	Defining the post-RA contaminant nature/extent
1994 DOE Box Investigation	Geophysical/soil gas surveys	Not performed under CERCLA; only "screening" data collected	Qualitatively for designing subsequent investigation/RA
1996 DOE Box Confirmation Sampling	13 discrete and composite samples	Data collected/validated to CERCLA standards; no significant quality issues	Defining the post-RA contaminant nature/extent
2002 DOE Box Follow-up Confirmation Sampling and DL Sampling	30 confirmation soil samples. Five PL soil samples from a 35 ft bgs boring and six from a 35.5 ft bgs boring, plus a grab ground water sample ⁽⁴⁾ from each boring (Tables 6-40 and 6-41 and Appendix J)	Data collected/validated to CERCLA standards; no significant quality issues	Defining the post-RA contaminant nature/extent
1987-1994 Ground Water Investigations/Monitoring	Periodic sampling of up to 23 wells and several privately owned supply wells (Table 2-2)	Not performed under CERCLA; no record of data validation	Qualitatively for selecting subsequent sampling locations
1995-2001 Ground Water Investigations/Monitoring	Periodic sampling of up to 46 wells and hydropunch sampling at 22 locations (Table 2-2)	Data collected/validated to CERCLA standards; no significant quality issues	Selected sampling points used semi-quantitatively for assessing impact to ground water by LEHR Federal Facility Areas
1996-2001 Storm Water Monitoring	Two storm events per year from LS-1	Data collected/validated to CERCLA standards; no significant quality issues	Defining water quality of storm water runoff from LEHR Federal Facility Areas
1990-1994 Putah Creek Monitoring	Quarterly sampling of three locations	Not performed under CERCLA; no record of data validation	Not used

Table 5-1. LEHR Federal Facility Data Set Useability (continued)

LEHR Federal Facility Data Set	Data Set Description⁽¹⁾	Data Quality⁽²⁾	Data Use for RI
1995-2001 Putah Creek Monitoring	Periodic sampling of three (through 1996), then four locations	Data collected/validated to CERCLA standards; no significant quality issues	Qualitatively to evaluate potential impact to surface water from LEHR Federal Facility
1995-1996 Air Baseline Sampling	Four on-site and one distant location (Table 2-3)	Data collected/validated to CERCLA standards; no significant quality issues	Defining baseline Site air quality
1997-1998 Air Site Monitoring	Four on-site and one off-site location (Table 2-3)	Data collected/validated to CERCLA standards; no significant quality issues	Defining baseline Site air quality
1998-2002 Air RA Monitoring	Four fixed and one mobile location for each RA (Table 2-3)	Data collected/validated to CERCLA standards; no significant quality issues	Defining air quality during RAs

Table 5-1. LEHR Federal Facility Data Set Useability (continued)

Notes

- (1) Reference in parentheses indicates location in this document where data sets are described in more detail.
- (2) Minor data quality issues (e.g., low percentages of qualified/rejected data) are not included in this table, but are summarized in Section 5 and Appendix A of this document.
- (3) For some COCs, the 1994 data were statistically different from the later background data. In these cases, the 1994 data were not used to develop the statistically-based background values. Most notable was Sr-90: 1994 results were significantly higher than subsequent results, most likely due to shorter count times and higher uncertainties.
- (4) Grab ground water samples were collected from open boreholes, not developed wells.

Abbreviations

C-14	carbon-14
CERCLA	Comprehensive Environmental Response, Compensation, and Liability Act
COC	constituent of concern
Cr-VI	hexavalent chromium
Cs-137	cesium-137
DL	designated-level
DOE	United States Department of Energy
DSS	domestic septic system
EDP	Eastern Dog Pens
Hg	mercury
LS	lift station
RA	removal action
Ra/Sr	radium/strontium
Ra-226	radium-226
SWT	Southwest Trenches
WDP	Western Dog Pens

6. NATURE AND EXTENT OF CONTAMINATION AND GROUND WATER IMPACT EVALUATION

6.1 Potential Source Evaluation and Removal Action Decision Process

The following subsections describe the nature and extent of contamination associated with the areas of the LEHR Federal Facility identified as having potentially impacted the environment (Table 6-1). These potential source areas (referred to as DOE RI Areas) are addressed in the following order: first, the waste treatment systems (Ra/Sr Treatment Systems and DSSs); then, the dog pen facilities (WDPs and EDPs); and, finally, the waste disposal areas (SWT and DOE Box). As shown on Table 6-1, remedial activities have been performed at almost all of the DOE RI Areas. For those areas, the RA activities are described and the nature and extent of contamination both before and after the RA is summarized. Post-RA potential for transport of remaining contaminants to underlying ground water is also discussed.

Based on data from all of the CERCLA investigations, compounds detected above background levels (Section 4.1) in each area were considered COCs for the RAs (WA, 2000c). The frequency and magnitude of detection of each COC varied among the RA areas. Only a few COCs were consistently detected throughout each area and/or were known to be released to the environment as a result of past operations. These COCs were considered “driver COCs”. In the SWT area, the driver COCs are Ra-226, Sr-90, chlordane, Cr-VI, nitrate, and Hg. In the Ra/Sr Treatment Systems area, the driver COCs are Ra-226, Sr-90, and nitrate. In the WDPs area the driver COCs are Ra-226 and Sr-90.

During the RAs, screening samples were collected and analyzed for the driver COCs, with the exception of Cr-VI and Hg in the SWT area (Section 6.6.3.1). The screening sample analytical results were used to guide excavation activities. A two-phased data evaluation approach was used to determine if the RAOs were achieved during each RA. The Phase I Data Evaluations occurred immediately following each RA while the excavations were open, and were based on analyses of screening samples collected during the RAs. Prior to backfilling the RA excavations, screening analytical results were presented to the LEHR RPMs to reach consensus on whether cleanup goals were attained for driver COCs. Following RPM concurrence, confirmation samples were collected, the excavations were backfilled and the Site was restored.

The confirmation sample frequency and locations were determined using the Noether Calculation, a random-start grid sampling approach. This statistical approach was taken from *Statistical Methods for Evaluating the Attainment of Cleanup Standards* (US EPA, 1994b), and is intended for use for those contaminants for which cleanup at or near background is desired (e.g., Ra-226) (WA, 2001d).

The Phase II Data Evaluations were completed after all analytical results from the RA confirmation sampling were received. The RAOs for these RAs were:

1. Lower the excess cumulative cancer risk to an individual from exposure to site contaminants to a nominal range of 10^{-4} to 10^{-6} , using 10^{-6} as the point of departure;
2. Reduce the cumulative non-cancer HQ to below one;
3. Mitigate potential future impact to ground water;
4. Mitigate potential ecological risks during and after the RA; and
5. Minimize impact to on-site University research.

The Phase II Data Evaluations assessed whether or not RAOs 1 through 3 had been achieved and included conducting a risk analysis and a DL analysis. For the WDPs, DL analysis was not performed because all COCs in soil from all depths sampled were statistically below the RASs, and all COCs in soil from greater than two ft bgs were statistically at background levels. The risk analysis consisted of:

- Calculating the reasonable maximum exposure (RME) concentration for each COC;
- For COCs with their lowest respective RBASs that are less than background, statistically determining if the COC exceeds background;
- Performing a risk analysis for all above-background carcinogens and non-carcinogens using the lowest RBAS values;
- Comparing RMEs to US EPA PRGs; and
- Completing a “hot measurement” analysis.

The DL analysis consisted of three phases:

- Phase A, Preliminary DL Analysis: Evaluate confirmation sampling results and identify DL COCs and hot spot areas;
- Phase B, Data Gaps Investigation: Collect additional vertical profile data, if needed, for each DL COC at the hot spot area; and,
- Phase C, Refined DL Analysis: Model and calculate the DL values that protect ground water using the vertical extent of DL COCs and area-specific lithologic column, and compare the results to actual COC concentrations remaining in soil.

6.2 Radium/Strontium Treatment Systems

6.2.1 Description and Operations

Animal Hospital (AH)-1 and AH-2 housed the beagles involved in the Sr-90 and Ra-226 studies, respectively. The majority of the animal remains were kept frozen on-site and were disposed at Hanford in 1990. Wastewater from the dog cages in AH-1 and AH-2 was treated by the Sr-90 and Ra-226 Treatment Systems, respectively. The former treatment systems are shown on Figure 6-1.

The Ra-226 Treatment System consisted of one 14,400 gallon septic tank, with two compartments separated by a weir, and an effluent distribution box (DB) feeding three dry wells and two leach trenches via distribution pipelines. The Ra-226 septic tank was located between AH-1 and AH-2 (Figure 6-1).

The three Ra-226 dry wells were installed to facilitate subsurface infiltration of wastewater. These dry wells, each with a diameter of about 2.5 ft, consisted of open boreholes filled with gravel to depths between about six and 40 ft bgs (WA, 1998a). Due to frequent exceedances of the infiltration capacity of the original dry well system, two horizontal cobble-lined leach trenches were added in 1965. The Southern Leach Trench (SLT) extended south from the dry wells and was about 140 ft long, three ft wide and 14 ft deep. The Northern Leach Trench (NLT) extended north from the dry wells and was about 40 ft long, three ft wide and 14 ft deep.

The Sr-90 Treatment System consisted of a series of nine interconnected tanks (Tanks A through I), an ion-exchange column, associated pump and piping, and a leach field (WA, 1998a). The tanks were constructed of concrete and coated with a plastic material. The total capacity of these tanks was 46,000 gallons. The ion-exchange column was used to remove Sr-90 from the wastewater prior to discharge into the leach field. In 1962, Building H-214 was built over the Sr-90 tanks and original leach field. During this period, an additional leach field was constructed to the east to augment the original field (Figure 6-1). Building H-214, which housed the ion exchange system, was demolished in 1995 as part of the AH-1/AH-2 D&D activities.

6.2.2 Pre-Removal Action Contaminant Distribution

All pre-RA investigations in the Ra/Sr Treatment Systems area are summarized in Table 6-2 and sample locations are shown on Figures 6-2 and 6-3. The maximum reported concentrations of all constituents detected above background in soil and waste samples at the Ra/Sr Treatment Systems area prior to the 1999/2000 RAs are presented in Table 6-3.

6.2.2.1 Treatment System Area

The maximum reported pre-RA Ra-226 concentration of 206 picoCuries per gram (pCi/g) was detected in a sludge sample collected from the Ra-226 treatment tank. This sample was representative of the waste removed for off-site disposal in 1993. Sludge samples collected from the

tank were collected for treatability (solidification) studies and disposal at Hanford. The highest Ra-226 concentration detected in soil prior to the RAs, 14.7 pCi/g in sample LEHR-S-422, was collected 9.5 ft bgs from the Ra-226 leach trench. The data collected prior to the RA suggested that the Ra-226 contamination was laterally confined to the vicinity of the Ra-226 dry wells, associated piping, and Ra-226 leach trenches.

The maximum reported pre-RA Sr-90 concentration of 18,600 pCi/g was detected in sludge samples LEHR-SL-002 and -003, collected from Tank A of the Sr-90 treatment tanks. The highest Sr-90 concentration detected in soil prior to the RAs, 1.82 pCi/g in sample LEHR-S-426, was collected 11 ft bgs, north of the Ra-226 DB.

The maximum reported pre-RA nitrate concentration of 736 mg/kg was detected in a soil sample collected 15 ft bgs from soil boring SB-28, located northwest of Dry Well 1. The pre-RA data suggested that the majority of the nitrate contamination was present in areas surrounding the Ra-226 dry wells and leach trenches.

6.2.2.2 Old Davis Road Area

As described in Section 2.3.4.3, several investigations of shallow sediment in storm water channels along Old Davis Road were conducted because of potential impact from known overflows of the Ra-226 treatment system. COCs detected above background in samples from the first investigation included Ra-226, Cs-137, Bi-212, Bi-214, Pb-214, arsenic, chromium, Hg, nitrate, and several pesticides. Of these, only Cs-137 exceeded two times its background in more than one sample. Consequently, subsequent investigations in this area focused on Cs-137 impact.

Ra-226 was detected above background in two surface and one 0.5 ft deep soil samples from the storm water channel near Dry Well 1 (Figure 6-1). Ra-226 concentrations in these samples ranged from 0.995 to 1.28 pCi/g. These results were slightly above the 0.75 pCi/g background; however, these samples were analyzed by an alpha spectrometry method with higher uncertainty than the gamma spectrometry method. The Ra-226 samples analyzed using the gamma spectrometer were also ingrown for a longer period of time, which was the method used to establish the Site background value.

6.2.3 Removal Action Summary

In 1992, approximately 40,000 gallons of low-level radioactive liquid and sludge waste were removed from the Ra-226 septic tank and Sr-90 "Imhoff" tanks. This waste was solidified on-site, properly packed in 55-gallon drums, and shipped to the DOE Hanford site for disposal. This occurred prior to the LEHR Federal Facility's listing on the NPL, and is not considered part of the CERCLA RAs.

To facilitate the cleanup process, the Ra/Sr Treatment Systems were divided into two areas (Figure 6-1). Ra/Sr Treatment Systems Area I consisted of a DB, piping, three dry wells, and the NLT and SLT. In addition, given the close proximity and connectivity of DST 2 to the Ra-226

Treatment System, it was also included in the Area I RA. Area I RA activities began in May 1999 and were completed by November 1999. Area II consisted of the Ra-226 Tank, the Sr-90 Tank, the Sr-90 Tank Leach Field and the influent tank piping. The Area II RA occurred from July to November 2000. The Ra/Sr Treatment Systems RAs were conducted according to the *Work Plan for the Removal Action at Southwest Trenches, Ra/Sr Treatment Systems, and Domestic Septic System Areas* (WA, 2000c) and are discussed in more detail the *Final Radium/Strontium Treatment Systems Removal Action Confirmation Report* (WA, 2001c). Based on the results of pre-RA investigations, the primary driver COCs for the 1999 and 2000 RAs were Ra-226, Sr-90 and nitrate. The RAS were used as screening criteria (SC) to guide the RAs, and represented either the lowest RBAS or background, whichever is greater. The SC for Ra-226, Sr-90 and nitrate were 0.75 pCi/g, 10 pCi/g and 36 mg/kg, respectively. Because the SCs used for all RAs are equivalent to the RASs, the term RAS is used in this report.

6.2.3.1 Removal Action Activities

The Area I RA was implemented in two phases. DST 2, associated piping, three upper (zero to ten ft bgs) dry well structures, and two leach trenches were removed during the first phase. A total of 804 cubic yards (cu yd) of material were removed and packaged for off-site disposal as LLW. Following removal of the subsurface structures and the surrounding contaminated soil, confirmation samples were collected and the area was backfilled and compacted to grade with clean fill.

The second phase of the Area I RA consisted of defining the extent of contamination surrounding the lower portions of the dry wells (10 to 40 ft bgs) and their removal. To delineate the lateral and vertical extent of contamination, soil samples were collected from the dry well sides in all four compass directions at four-foot intervals to the water table and analyzed for nitrate, Ra-226 and Sr-90.

Once the extent of the contamination was defined, the three cobble-filled dry wells were removed to an average depth of 42 ft using six- and ten-foot diameter augers. Figure 6-4 presents a cross-sectional view of the Ra-226 dry wells and leach field. Excavation screening samples were collected to guide soil removal. Confirmation samples were collected at the completion of the excavation activities. The lower portions of the dry wells were then filled with controlled low-strength material to eight ft bgs and backfilled and compacted to grade with clean fill. Approximately 1,275 cu yd of LLW (concrete, cobbles, soil) and 441 cu yd of overburden soil were removed during the Ra/Sr Treatment Systems Area I RA.

The Ra/Sr Treatment Systems Area II RA was also implemented in two phases. The Sr-90 Leach Field and influent piping associated with both the Ra-226 and Sr-90 Tanks were removed during the first phase of the RA. A total of 300 cu yd of material was removed and packaged for off-site disposal during the first phase. The second phase consisted of demolishing and removing the Ra-226 and Sr-90 Tanks and the surrounding soil. A total of 1,200 cu yd of material was removed and packaged for off-site disposal during the second phase of the excavation. The Areas I and II excavation limits are shown on Figure 6-5. Following removal of the subsurface structures and the surrounding soil, confirmation samples were collected. The area was then backfilled and compacted to grade with clean fill.

6.2.3.2 Air Monitoring Results

Air monitoring was conducted in the Ra/Sr Treatment System area before, during and after the RA. Statistical tests were conducted on these air monitoring data to determine if the concentrations of COCs in air were distinguishable from background or exceeded regulatory limits. Detailed descriptions of the sampling and analysis, statistical tests methods and results are presented in Appendix D of this report. Statistical analysis of on-site air monitoring data collected during the Ra/Sr Treatment Systems RAs indicated that ambient air concentrations did not exceed the background or applicable regulatory limits.

6.2.4 Post-Removal Action Contaminant Distribution

Following the Area I and Area II RAs, confirmation samples were collected from the excavation floor and sidewalls. Both random-based and discretionary hot-spot confirmation samples were collected to ensure attainment of cleanup goals using a statistically-based sampling design.

A total of 38 confirmation samples and four field duplicates were collected between one and 42.5 ft bgs from the Area I RA excavation. A total of 32 confirmation samples and four field duplicates were collected between 1.5 and 12 ft bgs from the Area II RA excavation. The confirmation sample locations are shown on Figure 6-5. All of the confirmation samples were analyzed for a full suite of analytes. Of the 173 analytes, 40 were detected above their respective lowest site-specific background concentration in one or more samples. Of those analytes statistically above background, none were above their respective lowest RBAS concentrations; Arsenic was above its residential and industrial PRGs; Sr-90 was above its residential PRG; Cs-137 in 4 of 70 samples was detected at concentrations above its PRG for industrial soil. Confirmation sample analytical results for samples with concentrations above background, PRGs and/or lowest RBASs are summarized in Table 6-4.

The maximum Ra-226 activity of 1.81 pCi/g was detected in sample SSRSC035, collected 42.5 ft bgs near the bottom of Dry Well 2. The sample with the maximum Sr-90 activity of 2.18 pCi/g, SSRSC043, was collected five ft bgs near the former location of the influent piping for the Sr-90 Tank. The maximum Hg concentration of 2 mg/kg was detected in samples SSRSC010 and SSRSC024, collected at 1 and 5.5 ft bgs, respectively, from the SLT, approximately 20 ft and 140 ft south of Dry Well 3, respectively. The sample with the maximum Cr-VI concentration of 0.841 mg/kg, sample SSRSC070, was collected seven ft bgs from the Sr-90 Leach Field under the former location of the strontium effluent pipe. The maximum nitrate concentration of 304 mg/kg was detected in sample SSRSC040, located 20 ft bgs in the sidewall of the Dry Well 2 excavation.

Eleven of the 22 maximum detected radionuclide activities were measured in sample SSRSC035 near the bottom of Dry Well 2. Sample SSRSC034, collected near the bottom of Dry Well 1, had a measured Pu-241 concentration of 11.49 pCi/g. Therefore, samples SSRSC034 and SSRSC035 were reanalyzed to further evaluate these results. Eleven of the 12 radionuclide reanalyses for sample SSRSC035 were below the original results. The Pu-241 reanalysis results for sample SSRSC034 were 0.48 to 0.79 pCi/g. These reanalysis results are summarized in Table 6-5.

The confirmation sample data indicate that all of the Sr-90 contamination above the RAS has been removed. With the exception of samples SSRSC035 and SSRSC039, the confirmation data also suggest that the Ra-226 contamination above the RAS has been removed. The Ra-226 confirmation data set is statistically indistinguishable from the LEHR site background data set (per the Wilcoxon Rank Sum [WRS] test), and therefore residual Ra-226 does not appear to be present above background (which for Ra-226 is the RAS) in the RA area. All of the Area II nitrate confirmation data were below the RAS. Eight Area I confirmation samples contained nitrate above the RAS, indicating that some residual nitrate contamination remains in that area.

A detailed confirmation sample data evaluation is presented in the *Final Radium/Strontium Treatment Systems Area Removal Action Confirmation Report* (WA, 2001c). This evaluation included a human health risk analysis, based on the site-specific lowest RBAS, and a DL analysis. Background comparisons were performed for ten COCs with an RBAS less than the background value. WRS Tests and Quantile Tests were used to perform background comparisons for antimony, barium, cadmium, copper, Pb, manganese, Hg, Ra-226, thorium-228 (Th-228), and thorium-232 (Th-232). All of these constituents with the exception of Hg passed the WRS and Quantile Tests and therefore were eliminated from the human health risk screening. The human health risk analysis indicated that the RA activities reduced the cumulative cancer risk to a nominal range of 10^{-4} to 10^{-6} . The risk analysis also determined that the non-cancer HQ was reduced below 1.0 for all COCs. A Hot Measurement Analysis was also conducted on the confirmation data. Hg was the only COC that failed the hot measurement analysis.

The preliminary DL analysis retained Cr-VI, nitrate, Hg, C-14 and Cs-137 as DL COCs. DL data gaps sampling was conducted at the Ra/Sr Treatment Systems area to provide additional information on the vertical distribution of Cs-137, C-14, Cr-VI, Hg and nitrate in soil. The two confirmation samples with the highest and second highest activities/concentrations for Cs-137, C-14 and nitrate (as indicated by the confirmation sample analytical data) were used to select boring locations (Figure 6-6). The confirmation sample locations with the three highest Cr-VI and Hg concentrations were selected for sampling. Sample location SSRSC035 was also re-sampled at 42.5 ft bgs and additional samples were collected at 45 and 47.5 ft bgs at the request of the RPMs due to an elevated Ra-226 concentration at the original 42.5 ft bgs sampling location. The samples were analyzed for the COC associated with each sampling location. The sampling approach is discussed in greater detail in the *Designated-Level Sampling and Analysis Plan Addendum for the Radium/Strontium Treatment Systems Area* (WA, 2001b).

The analytical results of the DL samples are presented in Table 6-6. As shown, C-14 results are below the LEHR background level of 0.13 pCi/g in all samples from both borings, with no obvious activity trend with depth. Cs-137 activities in boring DL-11 are above the LEHR background level of 0.00695 pCi/g at 11, 16 and 21 ft bgs; the maximum activity was measured at 0.664 pCi/g in the sample collected at 16 ft bgs. In boring DL-12, samples at 12 and 22 ft had slightly elevated Cs-137 activities. Cr-VI concentrations were detected above the background concentration of 0.054 mg/kg in all of the samples from all of the borings, with no obvious concentration trend with depth. Hg was detected above the 0.248 mg/kg background concentration in borings DL-7 and DL-8 at 31 ft and 7.5 ft, respectively. Nitrate was detected above the 36 mg/kg background concentration in one of three samples from boring DL-4 (41.5 mg/kg at 30 ft bgs), and in

five of six samples from boring DL-5 at concentrations ranging from 39.5 to 132 mg/kg, with no obvious concentration trend with depth. All of the Ra-226 results from boring DL-13 were below the background level of 0.75 pCi/g. In addition, the Ra-226 activities in boring DL-13 decreased with depth.

As described in the following section, the data collected during the DL sampling were used in vadose zone modeling to evaluate the potential adverse impacts to ground water. This evaluation was conducted using all validated data with accurate x,y,z coordinates that represent remaining (i.e., not excavated) material (see Section 4.4). These results are also discussed in the following section.

6.2.5 Ground Water Impact Evaluation

As noted above, the Ra/Sr Treatment Systems area COCs identified from the confirmation data DL screening that could potentially impact ground water are Cs-137, C-14, Cr-VI, Hg, and nitrate. Additional COCs identified through a second round of DL screening that considered all data that represent remaining (i.e., not excavated) material are Am-241, Ra-226, Th-228, cadmium and zinc. Vadose zone modeling (Section 4.3) was used to back-calculate soil concentrations for these constituents that could result in a peak ground water concentration at two goals: MCLs and background (Table 6-7). In addition, the modeling provided a time estimate to reach these peak ground water concentrations. These soil concentrations were then compared to the actual Ra/Sr Treatment Systems area soil concentrations to evaluate the likelihood of adverse ground water impact. The results of the initial DL analysis are discussed in detail in the *Final Radium/Strontium Treatment Systems Area Removal Action Confirmation Report* (WA, 2001c) and results of both the initial and follow-up DL analyses are summarized below.

In addition, actual ground water data collected since 1995 from the two nearest downgradient wells UCD1-005 and UCD1-21 (Figure 2-3) were compared to background, as defined by data from upgradient well UCD1-18 (Section 4.3). Unfortunately, UCD1-005 is usually dry and has not been sampled over the last six years; therefore, only data from well UCD1-21 were used to assess ground water impact downgradient of the Ra/Sr Treatment Systems. The results of this analysis for each of the DL COCs identified for the Ra/Sr Treatment Systems area is summarized below.

Based on the vadose zone modeling results, it is very unlikely that the low activities of Cs-137, Am-241, and Th-228 detected in Ra/Sr Treatment Systems soil samples would impact ground water above background or the MCL (Table 6-7). These modeling results are corroborated by ground water data for Cs-137 and Am-241 which show similar low or non-detectable levels in downgradient well UCD1-21 and background well UCD1-18. No Th-228 ground water data are available for these wells.

Modeling results indicate that C-14 remaining in the Ra/Sr Treatment Systems area soil could potentially impact ground water above background and the MCL but any impact would be highly localized. C-14 activity in ground water from downgradient well UCD1-21 has ranged from 105 ±63 to 177 ±69 picoCuries per liter (pCi/l), above the ground water background value of 3.5 pCi/l but well below the MCL of 2,000 pCi/l. The modeling results suggest that the above-background C-14

in well UCD1-21 may be the result of C-14 in Ra/Sr Treatment Systems area soils. However, the above-background C-14 detected in the Ra/Sr Treatment Systems area soil was highly localized at the southern end of the SLT at depths between five and 15 ft bgs. The quantity represented by this above-background C-14 is roughly approximated at only 35 mCi. This small quantity and the distance to UCD-21 (approximately 300 ft) suggest there may be other sources of the above-background C-14 in well UCD1-21.

Modeling results indicate that Ra-226 remaining in the Ra-226 seepage trench/dry well area could potentially impact local ground water above background but below the MCL. Ground water results for the nearest downgradient well (UCD1-21) indicate Ra-226 activities similar to those in background well UCD1-18.

Modeling results indicate that Hg, cadmium, and zinc remaining in Ra/Sr Treatment Systems area soil could potentially impact ground water above background, and locally above MCLs. However, the estimated travel time for these peak ground water concentrations is over 5,000 years. In addition, these metals are either not detected or are detected at levels below background in ground water from downgradient well UCD1-21.

As shown on Table 6-7, the maximum Cr-VI concentration detected in the confirmation samples exceeded the soil model result for ground water impact at the 39 micrograms per liter ($\mu\text{g/l}$) background level, but was below the soil model result for impact at the 50 $\mu\text{g/l}$ total chromium MCL. However, the confirmation sample reasonable maximum exposure (RME) concentration and all DL soil boring sample results were below both the background and MCL soil model results. Therefore, these confirmation and DL sample results indicate that any above-background impact to ground water from Cr-VI remaining in the Ra/Sr Treatment Systems area would be highly localized and would be below the total chromium MCL. In addition, the estimated time to peak Cr-VI concentration is 500 years. Although Cr-VI is detected at levels slightly above background (36 to 66 $\mu\text{g/l}$) in downgradient well UCD1-21, the modeling results and well location suggest that the Ra/Sr Treatment Systems are not the only source for these slightly elevated concentrations. Well UCD-21 is approximately 150 ft and not always directly downgradient from the area of above-background Cr-VI in Ra/Sr Treatment Systems soil, so other regional or Site Cr-VI sources may impact ground water at this location.

Modeling results indicate that nitrate remaining in the Ra/Sr Treatment Systems area soil could impact ground water above the 25.1 mg/l background and the 10 mg/l MCL. Nitrate concentrations as high as 64 mg/l have been detected recently in downgradient well UCD1-21. The modeling results suggest that the above-background and above-MCL nitrate in well UCD1-21 may be in part due to the nitrate in Ra/Sr Treatment Systems area soils.

Based on the DL evaluation and the ground water concentrations in downgradient well UCD1-21, Cr-VI Ra-226 remaining in soil in the Ra/Sr Treatment Systems area may impact local ground water above background but below the MCL, and remaining C-14 and nitrate may impact local ground water above background and the MCL. No other COCs remaining in Ra/Sr Treatment Systems area soil should have significant impact on ground water within the next several thousand years.

6.3 Domestic Septic Systems

6.3.1 Description and Operations

Seven known DSSs were located throughout the Site (Figure 1-2). Beginning in 1958, the DSSs served LEHR offices and laboratories. A typical DSS consists of a DST, leach field, and interconnecting piping. Liquid wastes and sewage were discharged to six of the seven DSTs (DSTs 1 through 6) prior to the Site's connection to the UC Davis Wastewater Treatment Plant in 1971. DSTs 1 through 6 were reportedly backfilled with sand and the influent/effluent lines for each tank were reportedly cut and capped in 1971 (IT Corp., 1996). No formal closure reports for these DSTs are known to exist (D&M, 1994). DST 7 was installed adjacent to the Co-60 Field to receive wastes from the irradiator building. This tank was reportedly never used.

Domestic septic system investigations are summarized in Table 6-8. Data were collected from the DSS areas during the LFI, Data Gaps Investigation, Ra/Sr Treatment Systems Area I RA, and the 2001 Domestic Septic System Investigation (DSSI). Details of the 2001 DSSI are presented in Appendix B of this RI. Although the Ra/Sr Treatment Systems were operating prior to DSS installation and therefore should have received all radionuclide waste, a wide variety of radionuclide and the chemical wastes may have been improperly disposed into the DSSs. Therefore, a broad suite of chemicals/radionuclides was analyzed for during the DSSI.

6.3.2 Domestic Septic Tank 1

6.3.2.1 Contaminant Distribution

Five soil samples (including one field duplicate) and one concrete sample were collected from the DST 1 area and analyzed for a full suite of constituents. The leach field for DSS 1 is discussed in Section 6.3.9. All of the chemical and radionuclide concentrations above their respective backgrounds and/or lowest RBASs at DST 1 are shown on Figure 6-7. All of the constituents with concentrations above their respective PRG are listed on Table 6-9. Of the 173 analytes, 10 were reported at concentrations above their respective background, two were detected at concentrations that exceed background and their lowest RBAS, four were reported at concentrations above background and the residential PRGs, and one was above background and the industrial PRGs. The concrete sample collected from the DST 1 interior tank floor had no constituents above their specific background and lowest RBAS values.

Ra-226 was detected slightly above its background and lowest RBAS at 0.78 pCi/g in soil sample LEHR-S-434, collected on the inlet side of DST 1 at 13 ft bgs. This sample activity is only 0.03 pCi/g above background. Manganese was detected in sample SSD1C001 at 890 mg/kg, above both the background and the lowest RBAS concentrations. However, this concentration is less than half the 1,800 mg/kg PRG for residential soil. Comparison of DST 1 area data to the lowest RBASs and PRG values indicates that COCs are not present at levels that pose a threat to human health. Therefore, no RA is planned at DST 1.

Preliminary DL analysis was conducted to identify COCs DST 1 that could potentially impact ground water (Appendix C). Based on this analysis, only Cr-VI is of potential concern. In October 2002, one DL boring was drilled at sample location SSD1C001 (Figure 6-7) where the maximum Cr-VI concentration was reported in the soil surrounding DST 1. Sample SSD1C001 was collected 8.7 ft bgs and DL samples were collected for Cr-VI analysis at five-foot intervals starting at 13.7 ft and terminating at 38.7 ft bgs.

The DST 1 DL sampling analytical results are presented in Table 6-10. Cr-VI concentrations were detected above the 0.054 mg/kg background concentration in all but one (SSDIDL06) of the samples from all of the borings, with no obvious concentration trend with depth.

6.3.2.2 Ground Water Impact Evaluation

To assess whether residual COC concentrations at DST 1 could potentially impact ground water, DL soil samples were collected at 8.7 and 13.7 ft bgs and analyzed using DI WET procedures for metals, SVOCs and nitrate. The goal in calculating DLs for solid waste is to determine concentrations of soluble constituents in the waste above which leachate would be able to carry them to ground or surface waters in amounts that would cause water quality goals to be exceeded in those waters (CRWQCB, 1989). DST 1 DI WET results are shown in Table J-1 of Appendix J. The DI WET results were directly compared to three water quality goals (background, MCLs, and tap water PRGs) to determine the soil's potential to degrade water quality. Direct comparison between the DI WET results and the water quality goals assumes an environmental attenuation factor of ten because the WET procedure requires the use of ten parts of water per every part of waste (e.g., soil).

The DST 1 DI WET results were first compared to background. The maximum detected concentration of each constituent detected in HSU 1 ground water well UCD1-18, located upgradient of the LEHR site, was used as the background concentration. If the DI WET results exceeded background, they were compared to the MCLs. Only chromium was detected above its background and MCL. Only iron was detected above background and its PRG. Assuming a 100-fold attenuation factor, all constituents were below their respective MCLs and/or PRGs, and only three constituents (copper, iron, and manganese) were above their respective background concentrations. Use of a "generic" 100-fold environmental attenuation factor provides an "average" degree of natural protection for water quality from the discharge of waste under reasonable worst-case conditions (CRWQCB, 1989).

A ground water sample was collected from the DL boring at sample location SSDIC001 (Figure 6-7). Table J-2 of Appendix J presents the analytical results for this sample that were above detection limits. The ground water samples were compared to background, MCLs and PRGs. Eight of the 21 COCs were detected above background. None of these COC concentrations was above its respective MCL. Three COCs, Pb, potassium-40 (K-40), and uranium-238 (U-238), were detected above their respective background concentrations and tap water PRGs. Uranium-233/234 (U-233/234), which does not have an established background concentration, was also detected above its PRG. The ground water sample at DSS 1 was collected from a borehole, not from a properly completed ground water well. The sample contained sediment soil particles and was not filtered in

the field or in the laboratory. Therefore, these ground water results represent overestimates of the actual ground water concentrations in this area.

The DSS 1 confirmation data indicated that only Cr-VI was present above background in soil, and therefore required modeling to assess potential ground water impact. Based on the modeling results (Table 6-11), the Cr-VI remaining in the DSS 1 area will not impact ground water above background or the MCL. In summary, DST 1 soil results, DL modeling, and DI WET analyses suggest that only copper, iron, and manganese may impact local ground water above background, and that any impact from COCs in the area would be below MCLs.

6.3.3 *Domestic Septic System 2*

6.3.3.1 **Removal Action Summary and Contaminant Distribution**

As discussed in Section 6.2.3.1, DST 2 was removed during the Ra/Sr Treatment Systems Area I RA. DST 2 was demolished using a hydraulic breaker attachment to the excavator. The tank was constructed of reinforced concrete, and was approximately eight ft wide by 16 ft long by 10 ft deep. The excavation in this area reached an approximate depth of 12 ft bgs. The top two to four ft of soil were classified as overburden to minimize the amount of low-level radioactive waste generated. The concrete, rebar, tank sediments and surrounding soil were packaged in B-25 boxes and disposed as LLW. Three confirmation samples were collected from the DST 2 excavation. These samples were included in the Ra/Sr Treatment Systems human health risk and DL analyses that are discussed in greater detail in Section 6.2.4. The DST 2 area was backfilled along the Ra/Sr Treatment Systems Area I excavation in 1999.

6.3.3.2 **Ground Water Impact Evaluation**

Potential impact to ground water from COCs originating from DSS 2 was evaluated as part of the Ra/Sr Treatment Systems DL analysis (Section 6.2.5). Based on the confirmation sampling results in the DSS area, no DL borings were located in this vicinity.

6.3.4 *Domestic Septic System 3*

6.3.4.1 **Pre-Removal Action Contaminant Distribution**

Table 6-12 summarizes all constituents detected in DSS 3 pre-RA soil samples at concentrations that exceed the lowest RBAS, background and/or the PRGs for residential soil. Cadmium, copper, Pb, manganese, Hg, silver and Ra-226 were detected above their respective soil backgrounds at depths greater than four ft bgs (>4 ft bgs) and lowest RBAS values. Seventeen constituents were detected above their respective PRGs for residential soil. The DSS 3 pre-RA sample locations where Hg and Ra-226 were detected are shown on Figure 6-8.

The DB sediment sample, SSD3C018, and the soil sample collected beneath the first point of perforation on the leach line, SSD3C020, had the maximum reported concentrations for the majority of the detected constituents (Figure 6-8). The maximum reported pre-RA Hg concentration, 751 mg/kg, was detected in the DB sediment sample (SSD3C018). Hg concentrations in soil ranged from 0.35 mg/kg to 498 mg/kg. Since only five soil samples were collected from the DSS 3 area, the extent of Hg contamination could not be determined.

Ra-226 was detected above the 0.75 pCi/g soil background in two of the DSS 3 investigation samples. The maximum reported pre-RA concentration of Ra-226, 2.44 pCi/g, was detected in soil sample SSD3C020, collected beneath the first point of perforation on the eastern leach line. The pre-RA data suggested that the Ra-226 contamination was limited to the DB sediment and immediately below the first point of perforation. Four SVOCs were reported in sample SSD3C022 at concentrations that exceeded their respective lowest RBAS values and PRGs for residential soil (Table 6-12). Sample SSD3C022 was collected 4.5 ft beneath the leach line midpoint.

6.3.4.2 Removal Action Summary

The DSS 3 RA was conducted between April and July 2002. The DSS 3 RA began with demolition and removal of the DB. All of the DB effluent lines were removed along with concrete, perforated Orangeburg pipe and leach trench gravel. Approximately one foot of additional soil from the trench floor and sidewalls was also removed. The DSS 3 leach trench excavation depth ranged from 11 to 12.5 ft bgs, and was up to eight ft wide and 50 ft long. Approximately 170 cu yd of removed piping, concrete, gravel and underlying soil are being managed as potentially mixed waste. Following waste removal, confirmation samples were collected and the area was backfilled and compacted to grade with clean fill.

6.3.4.3 Air Monitoring

Air sampling was conducted once during the DSS 3 and 6 RAs. Since there was only one sampling event, there were not adequate data to perform statistical tests. All of the maximum detected air concentrations were below the appropriate regulatory limits. The sampling and analytical results are described in Appendix D.

6.3.4.4 Post-Removal Action Contaminant Distribution

Following the DSS 3 RA, confirmation samples were collected from the excavation floor and sidewalls. At DSS 3, a total of 36 confirmation samples and 4 field duplicates were collected between 3.6 and 12.5 ft bgs (Figure 6-9). Three tank contents samples (including one field duplicate) and one concrete sample were also collected from the bottom of DST 3.

6.3.4.4.1 Soil

Of the 190 analytes, eight were detected above their respective background values (for greater than four ft bgs). Of those analytes that were above background, only Hg and formaldehyde were above their respective lowest RBAS concentrations. Confirmation sample analytical results for samples with concentrations above background, PRGs and/or lowest RBAS values are summarized in Table 6-13. All of the SVOC and VOC soil sample results were below the detection limits.

The maximum reported nitrate concentration, 106 mg/kg, was detected in sample SSD3C049, which was collected 12.5 ft bgs beneath the first points of perforation on the DSS 3 leach line (Figure 6-9). The six samples with the highest nitrate concentrations (45.2 to 106 mg/kg) were collected from the trench floor beneath the former location of the leach line at depths ranging from 11 to 13 ft bgs. The maximum reported Cr-VI concentration, 0.384 mg/kg, was detected in sample SSD3C046, collected 5.9 ft bgs from the leach trench's northern sidewall. Three of the four highest concentrations were detected in soil samples collected from the leach trench's northern sidewall. The maximum reported formaldehyde concentration, 2.2 mg/kg, was detected in sample SSD3C055, which was collected 12 ft bgs on the leach trench floor. Six of the seven maximum reported formaldehyde concentrations (1.1 to 2.2 mg/kg) were detected in soil samples collected 10 to 13 ft bgs.

The maximum detected total chromium concentration, 174 mg/kg, was detected in sample SSD3C047. Sample SSD3C047 was collected 5.9 ft bgs, from the northern sidewall of the leach trench. The ten highest chromium concentrations (131 to 174 mg/kg) were detected in soil samples collected from the excavation sidewalls at depths ranging from five to six ft bgs.

The maximum reported Hg concentration, 4.4 mg/kg, was detected in sample SSD3C066, collected 5.2 ft bgs on the leach trench's south sidewall (Figure 6-9). The seven highest Hg concentrations (2.4 to 4.4 mg/kg) were detected in soil samples collected five to six ft bgs. All of the Hg WET and TCLP results were well below the hazardous waste limit of 0.2 milligrams per liter (mg/l). Silver was reported above the detection limit in only 5 of 27 samples. The maximum reported silver concentration, 2.4 mg/kg, was detected in sample SSD3C053, collected 10.5 ft bgs from the leach trench floor.

The maximum reported alpha- and gamma-chlordane concentrations, 161 and 294 micrograms per kilogram ($\mu\text{g}/\text{kg}$), respectively, were detected in sample SSD3C047DL. This sample was collected 5.9 ft bgs from the leach trench's northern sidewall. The nine highest alpha and gamma chlordane concentrations were detected in samples collected between five and six ft bgs. Heptachlor epoxide was detected in only 1 of 27 soil samples. The maximum reported heptachlor epoxide concentration, 4 $\mu\text{g}/\text{kg}$, was detected in sample SSD3C061, collected 5.2 ft bgs from the leach trench's southern sidewall.

Cs-137 was measured above the detection limit in only 2 of 27 samples. The maximum reported Cs-137 concentration, 0.0139 pCi/g, was detected in sample SSD3C036. This sample was a discretionary sample collected 5.5 ft bgs, beneath the effluent line between DST 3 and the DSS 3 DB. Sample SSD3C036 was collected under the first pipe joint north of the DB. Pb-210 was detected in only 5 of 27 soil samples. The maximum reported Sr-90 concentration, 1.6 pCi/g, was detected in sample SSD3C056, collected 13 ft bgs from the leach trench floor. The five highest Sr-90 concentrations (0.597 to 1.6 pCi/g) were detected in samples collected between 10 and 13 ft bgs.

A detailed confirmation sample data evaluation is presented in the *Domestic Septic Systems 3 and 6 Removal Actions Confirmation Report* (WA, 2002a). This evaluation included a human health risk analysis based on the site-specific lowest RBASs, and a DL analysis. Background comparisons (WRS and Quantile Tests) were conducted on the cadmium, copper, Pb, Hg and Ra-226 confirmation

data sets. All of the constituents with the exception of Hg passed the background comparisons and were therefore eliminated from the human health risk screening. The human health risk analysis indicated that the RA activities reduced the cumulative cancer risk below 10^{-6} . The risk analysis also determined that the cumulative non-cancer RBAS HQ was 3.22 for the DSS 3 area. Hg was the most significant contributor to the cumulative HQ. A Hot Measurement Analysis was also conducted on the confirmation data. Hg and formaldehyde were the only COCs that failed the hot measurement analysis.

The DSS 3 preliminary DL analysis (WA, 2002b) identified 13 COCs that require additional evaluation: formaldehyde, Cr-VI, carbazole, arsenic, cadmium, chromium, Pb, Hg, molybdenum, nitrate, selenium, silver and Ra-226. The post-RA confirmation sampling and DL sampling data indicated that seven of the 13 DSS 3 DL COCs did not require further analysis by modeling. Arsenic, cadmium, Ra-226, selenium and Pb were not detected above background in any sample, and carbazole was not measured above the detection limit in any sample. Chromium was not detected above 197 mg/kg (background for 3.5 to 13 ft bgs) in any DSS 3 confirmation or DL sample. Therefore, modeling was not warranted for these constituents.

One DL boring was drilled at the first point of perforation on the eastern DSS 3 leach line at sample location SSD3C020 (Figure 6-8). DL samples were collected at one-ft vertical intervals between 13 and 17 ft bgs and analyzed for Hg. DL samples were collected at five-ft vertical intervals between 15 and 40 ft bgs and analyzed for Ra-226, formaldehyde, Cr-VI, nitrate, SVOCs and metals. The DSS 3 DL analytical results are shown in Table 6-14. Formaldehyde concentrations ranged from 0.19 mg/kg to 0.92 mg/kg, below the lowest RBAS of 1.7 mg/kg. Cr-VI concentrations were detected above background (0.054 mg/kg) in five of the six samples, but below the lowest RBAS, 3.8 mg/kg. The three maximum detected Cr-VI concentrations (0.322 to 0.387 mg/kg) were collected between 15 and 25 ft bgs. Hg was detected above the 0.248 mg/kg background concentration (for greater than 4 ft bgs) in one of 10 samples. The highest Hg concentration, 0.28 mg/kg, was collected at 14 ft bgs. Molybdenum concentrations ranged from non-detectable to 0.66 mg/kg. Four of six molybdenum samples are above the 0.26 mg/kg background concentrations, but below the PRG. All of the nitrate DL results are below the 36 mg/kg site background, with no obvious concentration trend with depth. Selenium was detected in only one of six samples at 0.86 mg/kg, which is below the 1.2 mg/kg site background concentration. All of the silver DL results are below the 0.56 mg/kg site background, with no obvious concentration trend with depth. As described in Section 6.3.4.5, the data collected during the DL and confirmation sampling were used in vadose zone modeling to evaluate potential adverse impacts to ground water.

6.3.4.4.2 Domestic Septic Tank 3

As discussed in Section 6.3.4.4, two tank contents samples were collected from the bottom of DST 3. Notable results of the analyses of these samples include:

- All of the SVOC and VOC results were below their respective detection limits.
- Hg, molybdenum, Cr-VI, silver and Cs-137 were the only analytes detected above the lowest site soil background values.

- The 3.2 and 1.1 mg/kg Hg concentrations reported in the tank contents exceeded the lowest site soil background value of 0.248 mg/kg and the DSS 3 area-specific Hg RBAS of 1.13 mg/kg.
- Cs-137 sediment concentrations of 0.0195 and 0.0108 pCi/g, were above the lowest site soil background value of 0.00695 pCi/g, but below the lowest RBAS of 0.1 pCi/g.
- Silver was detected above the site soil background of 0.55 mg/kg in one sediment sample at a concentration of 1.9 mg/kg.
- Molybdenum tank contents concentrations, 0.74 and 0.63 mg/kg, exceeded the site soil background concentration of 0.26 mg/kg.
- Cr-VI was detected at 0.124 mg/kg, above the site's soil background of 0.054 mg/kg, but below the lowest RBAS of 3.8 mg/kg.
- Gamma-chlordane was detected above the detection limit, but below the lowest RBAS, in one sediment sample at 47.8 µg/kg.
- Arochlor-1254, at 225 µg/kg, was the only PCB detected.

A concrete sample was collected from the bottom of DST 3. Notable results from this sample include:

- All SVOCs and pesticides results were below their respective detection limits.
- Molybdenum and thallium were the only analytes detected above the lowest site soil background values.
- Molybdenum was detected at 0.52 mg/kg above the soil background of 0.26 mg/kg.
- Thallium was detected at 2.8 mg/kg above the soil background of 1.6 mg/kg.
- Acetone at 30.9 µg/kg was the only VOC detected in DST 3 concrete. The acetone concentration detected in the concrete was well below the lowest RBAS value of 1,700 µg/kg.

6.3.4.5 Ground Water Impact Evaluation

To assess whether residual COC concentrations at DSS 3 could potentially impact ground water, DL soil samples were collected 13 and 17 ft bgs from the DL boring (Figure 6-8) and analyzed using DI WET procedures for metals, SVOCs and nitrate. DSS 3 DI WET results are shown in Table J-3 of Appendix J. The DI WET results were directly compared to three water quality goals (background, MCLs, and tap water PRGs) to determine the soil's potential to degrade water quality. As described in Section 6.3.2.2, this analysis assumes an attenuation factor of 10.

Only two DI WET constituents, arsenic and chromium, were detected above their respective backgrounds and MCLs. Iron was detected above background and its PRG. Several constituents did not have background and/or MCL values. Therefore, the DI WET results were also compared to their respective US EPA PRG for tap water. Pb, manganese and vanadium were detected above their MCL or PRG. Assuming a 100-fold attenuation factor (see Section 6.3.2.2), all constituents, with the exception of one iron sample, were below their respective backgrounds MCL, or PRG values. A ground water sample was collected from DL boring D3-DL1 collected at sample location SSD3C020 (Figure 6-8). Table J-3 of Appendix J presents the analytical results for this sample that were above detection limits. The ground water samples were compared to background, MCLs and PRGs. Three of 13 DL COCs, Cr-VI, carbazole and cadmium, were not measured above the detection limit. Arsenic and chromium were detected above their respective background values and MCLs, but below PRGs. Total Hg was detected above its MCL, but below the PRG. Iron, Pb, nickel and K-40 were detected above their respective PRG or MCL.

The ground water sample at DSS 3 was collected from a borehole, not from a properly completed ground water well. This sample contained sediment soil particles and was not filtered in the field or in the laboratory. Therefore, these ground water results represent overestimates of the actual ground water concentrations in this area.

As described in Section 6.3.4.4.1, DSS 3 confirmation data indicated that Hg, formaldehyde, Cr-VI, molybdenum, nitrate and silver were present above background and therefore required modeling. One DL boring was drilled at the first point of perforation on the eastern DSS 3 leach line at sample location SSD3C020 (Figure 6-8). DL samples were collected at one-ft vertical intervals between 13 and 17 ft bgs and analyzed for Hg. DL samples were collected at five-ft vertical intervals between 15 and 40 ft bgs and analyzed for Ra-226, formaldehyde, Cr-VI, nitrate, SVOCs and metals.

DL modeling results (Table 6-15) indicate that the residual Hg concentration in soil at DSS 3 might result in some measurable impact to ground water above the MCL and current background in more than 3,300 years. Hg has not been detected in downgradient wells UCD1-13 and UCD1-21 in the past six years.

Based on the DL modeling, localized impact on ground water may exceed the MCL and background for formaldehyde in DSS 3 soil. The peak impact is predicted to occur in approximately 10 years. However, formaldehyde has not been measured above the detection limit in downgradient wells UCD1-13 and UCD1-21.

All of the Cr-VI results from the confirmation and DL sampling are below the DL model results for ground water impact at background and MCL levels. Therefore, any impact on ground water from these Cr-VI concentrations in DSS 3 soil would be below the MCL and background. Although Cr-VI has been detected at levels slightly above background (36 to 94 µg/l) in downgradient wells UCD1-13 and UCD1-21, the modeling results and well locations suggest that DSS 3 area is not the only source for these slightly elevated concentrations. Wells UCD1-13 and UCD1-21 are approximately 300 ft from DSS 3. Since the ground water flow direction varies seasonally, these wells are not always directly downgradient from the DSS 3 area, and other regional or Site Cr-VI sources may impact ground water at this location.

The maximum molybdenum concentration detected in DSS 3 Area DL samples was 2.5 mg/kg. Based on the DL modeling, any impact on ground water from molybdenum in DSS 3 soil will be below the tap water PRG. The DL modeling indicated that localized impact on ground water may exceed current ground water background and that the peak concentration in ground water is occurring or has already passed. However, the concentration of molybdenum in the DL borehole ground water sample (16.7 µg/l) was within the range of background concentrations detected in upgradient well UCD1-18 (1.2 µg/l to 90 µg/l). Molybdenum has not been detected in downgradient wells UCD1-13 and UCD1-21 in the past six years.

The DL results indicate that 2.6 mg/kg nitrate in DSS 3 area soil may result in ground water impact equal to the 10 mg/l nitrate (as nitrogen) MCL (Table 6-15).

There are known regional nitrate impacts to ground water in the LEHR area from agricultural activities. For example, ground water from well UCD1-18, located approximately 500 ft upgradient of the LEHR site, has a nitrate concentration of 25 mg/l (80% LCL on 95th quantile of available data). Using this concentration as a ground water goal for the DL modeling results in an allowable soil concentration of 6.22 mg/kg. The nitrate background concentration for soil (36 mg/kg) is more than five times greater than the modeled DL concentrations.

The maximum nitrate concentration detected in DSS 3 confirmation soil samples was 106 mg/kg, and the RME concentration is 33.5 mg/kg. The DL sampling maximum result was 33.2 mg/kg, indicating that the soil column is not currently contaminated above soil background. Based on the DL modeling, localized impact on ground water may exceed the MCL and background from these concentrations of nitrate in DSS 3 soil. The peak impact is predicted to occur in approximately 13 years. The maximum detected nitrate concentrations from downgradient wells UCD1-13 and UCD1-21 are 19 and 64 mg/l, respectively, compared to the 25 mg/l background concentration. Other site and/or regional sources are likely the cause of the above-background concentrations in well UCD1-21.

Using the 100 µg/l MCL as the ground water goal, the DL modeling result for silver is 0.268 mg/kg in soil, with a peak ground water concentration equivalent to the MCL in 500 years. Using the 5 µg/l estimated background ground water concentration as a goal, the resulting DL soil limit is 0.143 mg/kg. The LEHR background soil concentration for silver is 0.55 mg/kg. The maximum silver concentrations detected in confirmation and DL samples were 2.4 mg/kg, and 0.37 mg/kg, respectively. Based on the DL modeling, silver in DSS 3 soil may locally impact ground water, but the impact would be expected to be below the MCL. Silver has not been detected in downgradient wells UCD1-13 and UCD1-21 in the past six years.

In summary, DSS 3 soil results, DL modeling, and DI WET analyses suggest that formaldehyde, molybdenum, nitrate, and silver may impact local ground water above background, and the impact from formaldehyde and nitrate may also be above MCLs. However, formaldehyde has not been detected in the nearest downgradient wells, and at least some of the nitrate detected in these wells originates from other known sources.

6.3.5 Domestic Septic System 4

6.3.5.1 Investigation Summary and Contaminant Distribution

A total of nine soil samples (including one field duplicate) were collected from the DSS 4 area. All of the chemical and radionuclide concentrations above their respective backgrounds and lowest RBASs at DSS 4 are shown on Figure 6-10. All of the constituents with concentrations above their respective PRG are listed on Table 6-9. Of the 173 analytes, 24 were detected above their respective background levels, 8 were detected at concentrations above background and residential PRGs, and four were detected in concentrations greater than background and the industrial PRGs.

Eight soil samples were analyzed for Hg. Six of these contained Hg in concentrations greater than both the background and the lowest RBAS concentrations. Pb was detected above the lowest RBAS and background in three of eight samples. The maximum reported Hg and Pb concentrations were detected in composite sample SSD4C002A/B at 3.5 mg/kg and 20.1 mg/kg, respectively. Sample SSD4C002A/B was collected from beneath the first points of perforation on the two DSS 4 leach lines (Figure 6-10). The second highest Hg and Pb concentrations were detected in Phase II sample, SSD4C005, collected directly beneath the leach line at the approximate midpoint of the southern leach line. The highest Hg and Pb concentrations were detected in the soil that was intermixed with the leach field gravel. The remaining samples show a trend of decreasing concentration with depth. All of the Hg and Pb concentrations were well below their residential PRGs of 23 mg/kg and 150 mg/kg, respectively.

Copper was detected above the lowest RBAS and background in sample SSD4C002A/B at 64.6 mg/kg, well below the 2,900 mg/kg PRG for residential soil. Th-234 was detected above the lowest RBAS and background in sample LEHR-S-401 at 4.15 pCi/g. U-235 was detected above the lowest RBAS and background in sample LEHR-S-T401 at 0.16 pCi/g as shown in Figure 6-10. The Th-234 and U-235 concentrations were below their PRGs of 1,330 and 0.195 pCi/g, respectively.

Comparison of DSS 4 area data to the lowest RBAS and PRG values indicates that COCs are not present at levels that pose a threat to human health. Therefore, no RA is planned at DSS 4.

Preliminary DL analysis was conducted to identify DSS 4 COCs that could potentially impact ground water (Appendix C). Based on this analysis, Cr-VI, chromium, Pb, Hg, and selenium are of potential concern. One DSS 4 DL boring was drilled at the first point of perforation on the western leach line at sample location SSD4C004 (Figure 6-10). A discrete sample from this location contained the maximum detected Cr-VI concentration at DSS 4, 0.925 mg/kg. A sample composited from this location and beneath the first point of perforation on the southern leach line contained the maximum Hg, Pb and selenium concentrations. Sample SSD4C004 was collected 7.8 ft bgs; therefore, DL samples were collected for Cr-VI, total chromium, Pb, Hg, and selenium analyses at five foot intervals starting 12.8 ft bgs and terminating 37.7 ft bgs.

The DSS 4 DL analytical results are presented in Table 6-10. Cr-VI was detected above the background concentration of 0.054 mg/kg in all except one of the samples from all of the borings, with no obvious concentration trend with depth. All of DSS 4 DL sampling Hg results were below the 0.248 mg/kg site background. Chromium was detected above the site background for greater

than four ft bgs, 125 mg/kg, in one sample. Sample SSD4DL02, collected 12.8 ft bgs, had a chromium concentration of 153 mg/kg. Pb and selenium were detected at concentrations that were slightly above their respective backgrounds, 9.5 and 1.2 mg/kg, respectively. Sample SSD4DL07, collected at 37.8 ft bgs, had a Pb concentration of 9.6 mg/kg. Sample SSD4DL03, collected 17.8 ft bgs, contained selenium at 1.3 mg/kg. None of the DL COCs showed a concentration distribution trend with depth.

6.3.5.2 Ground Water Impact Evaluation

To assess whether residual COC concentrations at DSS 4 could potentially impact ground water, DL soil samples were collected 7.8 and 12.8 ft bgs and analyzed using DI WET procedures for metals, SVOCs and nitrate. DSS 4 DI WET results are shown in Table J-5 of Appendix J. The DI WET results were directly compared to three water quality goals (background, MCLs, and tap water PRGs) to determine the soil's potential to degrade water quality. As described in Section 6.3.2.2, this assumes an attenuation factor of ten.

No DI WET constituent was detected above background and MCLs. Only iron was detected above background and its PRG. Assuming a 100-fold attenuation factor (see Section 6.3.2.2), all constituents were below their respective backgrounds, MCLs, and/or PRGs.

A ground water sample was collected from the DL boring at sample location SSD4C004 in the DSS 4 area (Figure 6-10). Table J-6 of Appendix J presents the analytical results for this sample that were above detection limits. The ground water samples were compared to background, MCLs and PRGs. Six of the 22 COCs were detected above background. None of these six COCs was detected above its respective MCL or PRG. Two COCs without established background values, U-233/234 and U-238, were detected above their PRGs. The ground water sample at DSS 4 was collected from a borehole, not from a properly completed ground water well. The sample contained sediment soil particles and was not filtered in the field or in the laboratory. Therefore, these ground water results represent overestimates of the actual ground water concentrations in this area.

DSS 4 soil sampling data indicated that Cr-VI, chromium, Pb, Hg, and selenium were present above background and therefore required modeling to evaluate potential impact to ground water. DL modeling results (Table 6-11) indicate that the residual Cr-VI in soil at DSS 4 might result in local impact to ground water above the background level and MCL. However, the nearest downgradient wells (UCD1-20 and UCD1-24) contain Cr-VI concentrations that are similar to those in background well UCD1-18 (Table 6-11).

The modeling results indicate that chromium, Pb, and Hg in DSS 4 area soil might impact local ground water above background, and that impact from chromium and Hg might be above MCLs. However, the time to peak impact from these COCs ranges from nearly 1,400 to 83,000 years, and there is no evidence of above-background impact to ground water in the nearest downgradient wells.

The modeling results also indicate that selenium in DSS 4 area soil will not impact ground water above background or the MCL. This is corroborated by ground water data from nearby

downgradient wells, which contains selenium concentrations similar to those in background well UCD1-18 (Table 6-11).

In summary, DSS 4 soil results, DL modeling, and DI WET analyses suggest that only Cr-VI may have local ground water impact above background within the next thousand years. Cr-VI may also have local impact above its MCL. However, Cr-VI concentrations in the nearest downgradient wells are at background levels.

6.3.6 Domestic Septic Tank 5

6.3.6.1 Investigation Summary and Contaminant Distribution

All of the DST 5 area chemical and radionuclide concentrations above their respective background, lowest RBAS, or MCL are shown on Figure 6-11. All of the constituents with concentrations above their respective PRG are listed on Table 6-9. One soil sample, SSD5C001, was collected from the DST 5 area and analyzed for a full suite of analytes. Of the 173 analytes, five were detected at concentrations above their respective background, only Hg was detected above background and the lowest RBAS, and no analyte was above background and the residential or industrial PRGs. Hg at 0.35 mg/kg in sample SSD5C001 was the only constituent detected above both background (0.22 mg/kg) and the lowest RBAS (0.248 mg/kg). This Hg concentration was well below the residential PRG of 23 mg/kg.

One water sample was collected from the eastern hatch of DST 5. Pb, chromium, antimony, barium, Hg, benzene and 1,2-dichloroethane were detected above their respective MCLs (Figure 6-11). Benzene was detected at 1.04 mg/l, over 200 times the MCL of 0.005 mg/l.

Preliminary DL analysis was conducted to identify COCs associated with DST 5 that could potentially impact ground water (Appendix C). Based on this analysis, Cr-VI and U-235 are of potential concern. In October 2002, DL sampling was conducted at sample location SSD5C001 (Figure 6-11), the sole soil sample collected from the DSS 5 area. Sample SSD5C001 was collected 7 ft bgs; therefore, DL samples were collected at five-foot intervals starting at 12 ft and terminating at 37 ft bgs.

The DST 5 DL sampling analytical results are presented in Table 6-10. Cr-VI concentrations were detected above the background concentration of 0.054 mg/kg in all of the samples from all of the borings, with no obvious concentration trend with depth. Uranium-235/236 (U-235/236) was measured above background in two DL samples. The maximum detected U-235/236 concentration, 0.0594 pCi/g, was measured in sample SSD5DL08, collected 37 ft bgs.

6.3.6.2 Ground Water Impact Evaluation

To assess whether residual COC concentrations at DST 5 could potentially impact ground water, DL soil samples were collected seven and 12 ft bgs and analyzed using DI WET procedures for metals, SVOCs and nitrate. DST 5 DI WET results are shown in Table J-7 of Appendix J. The DI WET results were directly compared to three water quality goals (background, MCLs, and tap

water PRGs) to determine the soil's potential to degrade water quality. As described in Section 6.3.2.2, this assumes an attenuation factor of 10.

Only two DI WET constituents, arsenic and chromium, were detected above their respective background and MCL concentrations. Arsenic and iron were detected above background and their PRGs. Aluminum, which does not have an established background level or MCL, was detected above its PRG. Assuming a 100-fold attenuation factor (see Section 6.3.2.2), all constituents were below their respective MCLs and/or PRGs, and only copper, iron, and manganese were above their respective background concentrations.

A ground water sample was collected from the DL boring in the DST 5 area (Figure 6-11). Table J-8 of Appendix J presents the analytical results for this sample that were above detection limits. The ground water samples were compared to background, MCLs and PRGs. Ten of 23 COCs were detected above their respective background levels. Of these, only thallium was above its MCL and/or PRG. Two COCs without established background levels, Th-230 and U-233/234, were detected above their PRGs. Note that the ground water sample at DST 5 was collected from a borehole, not from a properly completed ground water well. The sample contained sediment soil particles and was not filtered in the field or in the laboratory. Therefore, these ground water results represent overestimates of the actual ground water concentrations in this area.

DST 5 soil sampling data indicated that Cr-VI and U-235 were present above background and therefore required modeling to evaluate potential ground water impact. DL modeling results (Table 6-11) indicate that the residual Cr-VI and U-235 in soil at DSS 5 will not impact ground water above the background level or MCL. This is corroborated by Cr-VI and U-235 concentrations in the nearest downgradient well (UCD1-21), which are similar to those in background well UCD1-18 (Table 6-11). In summary, DST 5 soil results, DL modeling, and DI WET analyses suggest that only copper, iron, and manganese may impact ground water above background levels, and that no DST 5 area COCs are expected to impact ground water above MCLs.

6.3.7 Domestic Septic System 6

6.3.7.1 Pre-Removal Action Contaminant Distribution

Table 6-16 summarizes all constituents detected in DSS 6 pre-RA soil samples at concentrations that exceed the lowest RBAS, background and/or the PRGs for residential soil. Antimony, barium, copper, Pb and Hg were detected above their respective soil background (> 4 ft bgs) and lowest RBAS values. Fifteen constituents were detected above their respective PRGs for residential soil. The DSS 6 pre-RA sample locations are shown on Figure 6-12.

Hg was detected above background and the lowest RBAS in 34 of 44 samples in concentrations ranging from 0.13 to 101 mg/kg. The pre-RA data suggested that the lateral extent of contamination was limited to the areas surrounding the leach lines.

Four SVOCs were detected above their respective lowest RBAS and PRG values for residential soil in sample SSD6C001A/B (Table 6-16). This two-point composite sample was collected beneath the first points of perforation on the northern leach lines.

Since there are no established background values for concrete, the analytical results from the DST 6 concrete tank bottom sample were compared to the lowest site soil background values. Cr-VI, at 0.13 mg/kg, was the only constituent detected above the lowest site soil background in the concrete sample. However, the Cr-VI concentration was well below the lowest RBAS and residential PRG concentrations.

6.3.7.2 Removal Action Summary

The DSS 6 RA consisted of removal of all the effluent lines, perforated Orangeburg pipe and leach trench gravels. Approximately one ft of additional soil from the trench floor and sidewalls was also removed. The excavation depth ranged from 6 ft bgs to 7 ft bgs and was 11 ft wide by 105 ft long. Approximately 215 cu yd of removed piping, gravel and underlying soil are being managed as potentially hazardous waste. Following waste removal, confirmation samples were collected and the area was backfilled with clean fill and compacted to grade.

6.3.7.3 Air Monitoring

Air sampling was conducted once during the DSS 3 and 6 RAs for health and safety purposes. Since there was only one sampling event, there were not adequate data to perform statistical tests. All of the maximum detected air concentrations were below the appropriate regulatory limits. A detailed description of the sampling and analytical results is presented in Appendix D.

6.3.7.4 Post-Removal Action Contaminant Distribution

Twenty-three confirmation samples and three field duplicates were collected from the DSS 6 excavation and analyzed for Cr-VI, copper, barium and Hg. Four additional discretionary samples were collected and analyzed for Hg. The confirmation sample locations are shown on Figure 6-13.

Of the 117 analytes, only Cr-VI and Hg were detected above their background values (for greater than four ft bgs). Hg was above the area-specific RBAS of 0.77 mg/kg but below the residential PRG of 23 mg/kg. Cr-VI concentrations were below the lowest RBAS of 3.8 mg/kg, and PRG of 30 mg/kg. Analytical results for confirmation samples with concentrations above background, PRGs and/or the lowest RBAS values are summarized in Table 6-17. All of the SVOC and VOC soil sample results were below the detection limits.

The maximum reported Cr-VI concentration was detected in sample SSD6C023, collected 4.4 ft bgs from the excavation sidewall east of the northeastern leach line's former location. Five of six samples with Cr-VI detections were collected from the excavation's eastern sidewall.

The maximum reported Hg concentration, eight mg/kg, was detected in soil sample SSD6C038, collected seven ft bgs beneath the former location of the DSS 6 northeastern leach line.

The second highest Hg concentration, seven mg/kg, was detected in soil sample SSD6C025, s collected 4.4 ft bgs, approximately seven ft west of sample SSD6C038 (Figure 6-13). No obvious concentration trends with depth were observed in the DSS 6 Hg data. All of the Hg WET and TCLP results were well below the hazardous waste limit of 0.2 mg/l.

A detailed confirmation sample data evaluation is presented in the *Domestic Septic Systems 3 and 6 Removal Actions Confirmation Report* (WA, 2002a). This evaluation included a human health risk analysis, based on the site-specific lowest RBAS, and a DL analysis. Background comparisons (WRS and Quantile Tests) were conducted on the barium, copper and Hg confirmation data sets. All of these constituents with the exception of Hg passed the WRS and Quantile Tests and therefore were eliminated from the human health risk screening. The human health risk analysis indicated that the RA activities reduced the cumulative cancer risk below 10^{-6} . The risk analysis also determined that the cumulative non-cancer RBAS HQ was 2.5 for the DSS 6 area, with Hg the most significant contributor to the cumulative HQ. Hg was the only COC that failed a Hot Measurement Analysis of the confirmation data.

The DSS 6 preliminary DL analysis (WA, 2002b) identified three COCs that require additional evaluation: Cr-VI, copper and Hg. All of the copper and nitrate results were below background. Therefore modeling for these constituents was not warranted. The DSS 6 DL results are shown in Table 6-18. Borings were also drilled at the first points of perforation on the southeastern and northeastern DSS 6 leach lines (Figure 6-12). At each boring, DL samples were collected at 1-ft vertical intervals from 6 to 10 ft bgs and at 5-ft vertical intervals from 10 to 40 ft bgs and analyzed for Hg. Samples were also collected at 5-ft vertical intervals from 6 to 41 ft bgs and analyzed for nitrate, total nitrogen, ammonia, copper, and Cr-VI.

Cr-VI was detected above background in 15 of 16 DL soil samples. No obvious concentration trend with depth was observed. Hg was detected above the 0.248 mg/kg background concentration (for greater than four ft bgs) in eight of the 27 samples, not including field duplicates. Five of eight samples that had Hg concentrations above the background had high matrix spike recovery. The DSS 6 DL mercury samples were recollected to further assess these results. The original samples, SSD6DL05, SSD6DL07, SSD6DL09, SSD6DL13, and SSD6DL15 contained Hg concentrations of 4.3, 3.6, 6.3, 0.94 and 0.53 mg/kg, respectively. Recollected samples SSD6DL05RE, SSD6DL07RE and SSD6DL20, SSD6DL09R, SSD6DL13RE, SSD6DL15RE contained below background Hg in concentrations of 0.14, 0.12 and 0.043 mg/kg, respectively. An additional DL boring was also drilled at confirmation sample location SSD6C038 where the maximum Hg concentration, eight mg/kg was detected. All of the Hg concentrations were below the 0.248 mg/kg background with the exception of sample SSD6DL44, where 0.72 mg/kg was detected. The highest Hg concentrations were observed between 10 and 20 ft bgs. As described in Section 6.3.7.5, the data collected during the DL and confirmation sampling were used in vadose zone modeling to evaluate the potential adverse impacts to ground water.

6.3.7.5 Ground Water Impact Evaluation

DSS 6 DL samples collected six and 10 ft bgs were analyzed using DI WET procedures for metals, SVOCs and nitrate. All detected DI WET analytes at DSS 6 are shown in Table J-9 of

Appendix J. DSS 6 DI WET results were evaluated following the methods described in Section 6.3.2.2. Only four constituents, arsenic, Pb, Cr-VI and total chromium, were detected above their respective background and MCL values. Pb was detected above its MCL in one sample. Assuming a 100-fold attenuation factor (see Section 6.3.2.2), arsenic, Pb and chromium were below their respective background and MCL values.

Several constituents do not have background or MCL values. Therefore, the DI WET results for these constituents were compared to their respective US EPA PRG for tap water. Aluminum, Cr-VI and iron were detected above their respective tap water PRG. Assuming a 100-fold attenuation factor, all of these constituents were below their respective PRG.

Two ground water samples and one field duplicate were collected from the DL borings at DSS 6. Table J-10 of Appendix J presents the analytical results that were above detection limits. All of the Hg concentrations were below the MCL. Cr-VI was detected in one sample at 0.051 mg/l, which is slightly above the 0.1 mg/l MCL. Copper was detected in two samples. The maximum detected copper concentration, 2.6 mg/l, is twice the 1.3 mg/l MCL. Two nitrate samples were above the MCL, but below background.

Arsenic, barium, chromium, cadmium, Pb and selenium were detected above their respective background and MCL values. Iron, beryllium, chromium, cadmium, Pb, nickel, K-40 vanadium lead-212 (Pb-212), and Ra 226 were detected above their respective MCL and/or PRG.

The ground water samples at DSS 6 were collected from a borehole, not from a properly completed monitoring well. These samples contained sediment/soil particles and were not filtered in the field or in the laboratory. Therefore, these ground water results represent overestimates of the actual ground water concentrations in this area.

Cr-VI and Hg were the only constituents detected above background in the DSS 6 confirmation and DL data sets and therefore require modeling. The DL modeling results for Cr-VI indicate that a soil concentration of 0.809 mg/kg distributed throughout the vadose zone may result in ground water impact at the 50 µg/l MCL (Table 6-19). In addition, the modeling results indicate that a soil concentration of 0.638 mg/kg might impact ground water at the estimated 39 µg/l background level. The maximum Cr-VI concentrations detected in confirmation and DL samples were 0.362 mg/kg, and 0.467 mg/kg, respectively. Based on the DL modeling, any impact on ground water from these concentrations of Cr-VI in DSS 6 soil will be below the MCL and background. Although Cr-VI is detected at levels slightly above background (36 to 66 µg/l) in downgradient well UCD1-21, the modeling results and UCD1-21 well location suggest that DSS 6 area is not the source of these slightly elevated concentrations. Other regional or LEHR Site sources may impact ground water at this location.

Using the 11 µg/l PRG for the more mobile mercuric chloride as the ground water goal, the DL modeling result for Hg is 0.522 mg/kg in soil, with a peak ground water concentration equivalent to the MCL in 1,860 years. Using the 0.10 µg/l estimated background ground water concentration as a goal, the resulting DL soil limit is 0.00475 mg/kg. The maximum Hg concentrations detected in confirmation and DL samples were 8.0 mg/kg, and 6.7 mg/kg, respectively, and the RME

concentration was 1.85 mg/kg. Based on the DL modeling, localized impact on ground water may exceed the MCL and background from these concentrations of Hg in DSS 6 soil. Hg has not been detected in downgradient well UCD1-21 in the past six years.

In summary, DSS 6 soil results, DL modeling, and DI WET analyses suggest that only Hg is expected to impact ground water above background and/or MCL, and that this impact will not occur for approximately 1,800 years.

6.3.8 Domestic Septic System 7

As discussed in Section B-9 of Appendix B, it is believed that DST 7 was demolished in place, possibly during installation of the existing sewer line at the Co-60 Building. Three soil samples were collected from the suspected former location of DST 7 during the LFI. All of the chemical and radionuclide concentrations above their respective backgrounds and/or lowest RBASs at DSS 7 are shown on Figure 6-14. Of the 169 analytes, 14 were detected above background, four were reported at concentrations above background and their lowest RBAS, three were above background and their respective residential PRGs, and two were above background and their industrial PRGs.

Sample LEHR-S-428, collected seven ft bgs, contained manganese at 790 mg/kg. This concentration is greater than both the background and lowest RBAS values, but less than half of the soil PRG for residential soil. Sample LEHR-S-429 had a Hg concentration of 0.35 mg/kg, slightly greater than the lowest RBAS value of 0.22 mg/kg and background concentration of 0.248 mg/kg, but well below the residential PRG of 23 mg/kg.

Ra-226 was detected above both background and the lowest RBAS at 0.85 pCi/g in Sample, LEHR-S-430. This activity is just 0.1 pCi/g above the background activity. Furthermore, the Ra-226 decay daughters, Pb-214 and bismuth-214, were well below background. The decay daughters should be in equilibrium with Ra-226; therefore, it is likely that the above-background Ra-226 activity is due to laboratory error.

UC Davis personnel indicate that before DSS 7 was used, the Co-60 Building was connected to the new sewer (WA, 2001g). No reports or drawing of a possible DB or leach field associated with DSS 7 have been found. The limited data available suggest that there are no constituents present at levels significantly above the lowest RBASs and background levels. Therefore, no further action is planned at DSS 7.

6.3.9 Domestic Septic Systems 1 and 5 Leach Field (Dry Wells A through E)

6.3.9.1 Removal Action and Investigation Summary and Contaminant Distribution

During the 1999 Ra/Sr Treatment Systems Area I RA, exploratory trenching was conducted to confirm the termination point of the Ra-226 NLT. On July 26, 1999 a concrete structure was

uncovered approximately 15 ft north of the NLT. Additional excavation in this area revealed a leach system containing five dry wells (Dry Wells A through E), a DB and piping connecting the system (Figure B-1). Based on a review of existing site maps, it is believed that the dry wells were used as the leachfields for DSSs 1 and 5 from 1962 to 1970 when the sanitary sewer system was connected. It is likely that DSSs 1 and 5 both served ITEH's Main Office and Laboratory (Building H213), where DOE-funded research was being conducted.

The dry well structures consisted of circular concrete manways 30 inches in diameter that extended from one to six ft bgs. Two-inch diameter rounded drain rock filled the manway structure starting at a depth of three ft bgs and continuing to eight ft bgs. In Dry Wells D and A, large cobbles 6 to 12 inches in diameter were observed between seven and eight ft bgs. The upper portions of Dry Wells A through E were removed to depths ranging from 8 to 20 ft bgs. Excavation in the vicinity of Dry Wells A, B, C, and E reached a depth of eight ft bgs. Dry Well D was excavated to a depth of 20 ft bgs, the maximum reach of the excavator. Gravel was observed to the maximum excavation depth indicating that Dry Well D is at least 20 ft deep. A DB was located approximately one ft bgs and measured four ft wide by four ft long by three ft high. The DB was removed and the area was excavated to a depth of approximately 5.5 ft bgs. The soil and rock were containerized in 13 B-25 boxes for proper characterization and disposal. The concrete removed from this area was pulverized and added to the WDPs concrete stockpile. Following excavation and waste removal, the area was backfilled and compacted using an excavator with a compaction wheel. DSTs 1 and 5 and the residual lower portions of the dry wells were not removed during this RA.

During the RA, 11 investigation samples were collected from the DSS 1 and 5 Leach Field (Dry Wells A through E) area. The analytical results are summarized in Table 6-20. The maximum Ra-226 and Cs-137 concentrations and the majority of the maximum detected metals concentrations were reported in sample CWRSC024, collected 9.5 ft bgs at the southwestern edge of Dry Well D. All of the soil within an approximate five-ft radius of sample CWRSC024 was removed during the 1999 RA.

Soil samples were collected during the 2001 DSSI to further characterize the occurrence, if any, of COCs at Dry Wells A through E. Soil samples were collected at 10, 20, 30, and 40 ft bgs from a borehole located approximately two ft from the axis of each dry well. All of the analytical results above background and the lowest RBAS levels at Dry Wells A through E are shown on Figure 6-15. All of the constituents with concentrations above their respective PRG are listed on Table 6-9. Of the 173 analytes, 24 were detected at concentrations greater than their respective backgrounds, seven were detected above their respective background and lowest RBAS, four were reported at concentrations that exceeded their respective background and residential PRG, one was detected above background and the industrial PRG.

At Dry Well A, cadmium, Cs-137, Hg and silver were detected at concentrations greater than both their respective background and lowest RBAS values. Hg was the only constituent to be detected above both background and the lowest RBAS concentrations in more than one sample. The Hg concentrations of 1.2 and 1.7 mg/kg were over four times greater than the background concentration of 0.248 mg/kg. The maximum reported cadmium concentration of 0.54 mg/kg was

only 0.03 mg/kg above background. Silver was detected at 7 mg/kg, over 1.5 times the lowest RBAS value. Cs-137 was detected at 0.191 mg/kg, 0.091 mg/kg greater than the lowest RBAS value.

At Dry Well B, cadmium, Cs-137, manganese, Hg and silver were detected at concentrations greater than both their respective background and lowest RBAS concentrations (Figure 6-15). Hg was detected at concentrations above both background and the lowest RBAS in three of four samples. The maximum reported Hg concentration of 0.49 mg/kg, was less than two times the background concentration. Maximum cadmium, Cs-137, manganese and silver concentrations were all less than two times their background or lowest RBAS.

At Dry Well C, barium, cadmium, Pb, manganese, Hg and silver were detected in concentrations greater than both their respective background and lowest RBAS levels (Figure 6-15). Hg was detected in concentrations above both background and the lowest RBAS in all four samples. The maximum reported Hg concentration of 1.5 mg/kg was over six times the background concentration. Silver was detected at concentrations above both background and the lowest RBAS in three of four samples. The maximum reported silver concentration of 53.8 mg/kg was over fourteen times the lowest RBAS concentration of 3.8 mg/kg. The maximum reported barium concentration of 608 mg/kg was over two times background. Maximum cadmium, manganese and Pb concentrations were all less than 1.5 times their background concentrations.

A total of four soil borings were drilled surrounding Dry Well D to determine if the 1999 RA successfully removed contamination near sample CWRSC024. Borings D1, D2, D3 were drilled southeast, southwest and northwest of the center of the Dry Well D, respectively (Figure 6-15). Samples were collected from borings D1, D2 and D3 at 10, 15 and 20 ft bgs and analyzed off-site for metals. Soil boring D4 was drilled northeast (down gradient) of Dry Well D, and samples were collected at 10, 20, 30 and 40 ft bgs and analyzed for a full suite of analyses. All of the borings were drilled within two ft of the axis of the dry well.

Pb and manganese were detected in concentrations greater than both their respective background and lowest RBAS values in samples collected from boring D1 (Figure 6-15). Manganese was detected above both background and the lowest RBAS in all three samples. The maximum reported manganese concentration of 1,010 mg/kg, is less than one and a half times the background concentration. The maximum reported Pb concentration, 9.9 mg/kg, was slightly above the background concentration of 9.5 mg/kg.

Hg and silver were detected in concentrations greater than both their respective background and lowest RBAS values in samples collected from borings D-2 and D-3. Hg was detected above both background and the lowest RBAS in four of six samples at 10 and 15 ft bgs. The maximum reported Hg concentration of 1.4 mg/kg is over five times the background concentration. Silver was detected above both background and the lowest RBAS in three of six samples. The maximum reported silver concentration of 27.6 mg/kg was over seven times the lowest RBAS concentration.

Hg was only constituent detected at a concentration greater than both background and the lowest RBAS levels in samples collected from boring D4. The Hg concentration of 1.5 mg/kg was over six times the background concentration of a depth between 38 and 42 ft .

At Dry Well E, Hg and silver were detected at concentrations greater than both their respective background and lowest RBAS levels. The maximum reported Hg concentration of 0.45 mg/kg was less than two times the background concentration. The maximum reported silver concentration of 6.7 mg/kg was less than two times the lowest RBAS.

A human health risk analysis was conducted on the Dry Wells A through E sample results and is discussed in detail in Appendix F. Background Comparisons (WRS and Quantile Tests) were conducted for barium, copper, Pb, mercury, manganese, Th-232, cadmium, Pb-210, Th-228 and Th-232. Barium, manganese, Pb-210, Th-228 and Th-232 passed their respective background comparisons and were removed from the human health risk analysis.

At Dry Wells A through E, Pb exceeded the 10^{-6} and 10^{-5} target risk levels for Scenario 1 and Scenario 2, respectively. For exposure Scenario 1, at 10^{-5} and 10^{-4} target incremental carcinogenic risk levels, the cumulative RME/RBAS ratio are below 1.0 for the Dry Wells A through E area. For exposure Scenario 2, at 10^{-4} target incremental carcinogenic risk level, the cumulative RME/RBAS ratio is below 1.0. For exposure Scenario 2, the RME/RBAS ratio for Pb accounted for 68.18 of 70.85 of the cumulative RME/RBAS. However a histogram comparison of the Dry Wells A through E Pb data and the background data set show that the Dry Wells A through E data is just slightly above background (Figure F-3). For exposure Scenario 3, the cumulative RME/RBAS ratio are below 1.0 for the 10^{-6} , 10^{-5} , or 10^{-4} target risk levels.

Cadmium, copper, Hg and silver had RME values that exceeded their respective non-carcinogenic RBAS values based on an HQ of 1.0. Scenario 2 (East side Residential Farmer) is the only scenario with a cumulative HQ that exceeded 1.0. The cumulative HQ for Scenario 2 is 10.42 with Hg and silver contributing fractions of 3.64 and 3.61, respectively.

6.3.9.2 Ground Water Impact Evaluation

Preliminary DL analysis was conducted to identify COCs associated with Dry Wells A through E that could potentially impact ground water (Appendix C). Based on this analysis, Cr-VI, chromium, Hg, molybdenum, silver, Cs-137, and Sr-90 are of potential concern (Table C-1). Because the maximum concentrations of all of these COCs were detected at depths typically below the water table (i.e., 30 ft bgs or greater), vadose zone modeling was not needed to evaluate potential impact to ground water. Instead, "equilibrium soil concentrations" were calculated using the ground water background levels, MCLs and representative partitioning coefficients (K_d) for these COCs. The results of these calculations and comparisons of the equilibrium soil concentrations with the maximum concentrations detected in the Dry Wells A through E area are presented in Table 6-21.

As shown on Table 6-21, all of the DL COCs in the Dry Wells A through E area are present at concentrations that could result in localized ground water impact above background. In addition, the maximum Cr-VI, total chromium, Hg, and silver concentrations could also result in ground water impact above MCLs. With the exception of Cr-VI, none of these COCs has significantly impacted ground water at the LEHR Site, and there are other known sources for Cr-VI in ground water. However, the nearest downgradient wells are at least 400 ft from the Dry Wells A through E area, making local impact to ground water from the Dry Wells difficult to assess.

6.4 Western Dog Pens

6.4.1 Description and Operations

Following a 30-day indoor holding period, the irradiated beagles were moved outside to the WDPs and EDPs (Figures 1-2, 6-16 and 6-17) (Goldman, 1997; DOE archived records). Feces were removed from each pen daily, and urine percolated into the gravel floor of the dog pens (Ballard, 1997; Goldman, 1997; Hinz, 1997; DOE archived records). The gravel was removed periodically and disposed in the SWT (Hinz, 1997) and possibly disposed off-site (Ballard, 1997). Dogs were dipped in chlordane to control fleas from 1960 until 1968, when excess exposure to chlordane appeared to have impacted the health of the dogs (DOE archived records). The dipping was apparently performed near the western boundary of the WDPs (Goldman, 1997; Hinz, 1997). Chlordane was also sprayed in and around the dog pens, particularly near the southern edge of the pens because flea-bearing rodents were believed to be more plentiful south of the dog pens than in other directions due to the proximity of Putah Creek (Ballard, 1997).

From available architectural drawings and LEHR documents, the following dog pens construction timeline was developed. By June 1958, 64 outside pens (Rows A and B, Figure 6-16) were completed in the WDPs area, with the exception of dog house installation and surfacing with crushed rock. These outside pens were scheduled to be completed and occupied by September 1958 (DOE, 1958). By 1960, 96 outdoor pens (Rows A through C) were completed and put into operation (DOE, 1961). By February 3, 1961, 128 pens (Rows A through D) were complete. Based on field investigations, these original four rows, A through D, contain sub-grade, gravel-filled trenches that are oriented in an east-west direction. Construction drawings indicate that these trenches contain a water line, but their design purpose is not known. Between 1961 and 1964, an additional 64 pens were constructed (Rows E and F) for a total of 192 pens. Between 1964 and 1968, the remaining 128 WDPs were constructed (Rows G through J). In rows E through J of the WDPs, the water lines were not buried in gravel trenches. The WDPs were used to house research animals through 1988 when DOE-funded research activities ceased.

6.4.2 Pre-Removal Action Contaminant Distribution

All pre-RA investigations in the WDPs area are summarized in Table 6-22 and sample locations are shown on Figures 6-18 and 6-19. A statistical evaluation of the pre-RA WDPs soil analyses was presented in the *Draft Technical Memorandum: Statistical Comparison of Western Dog Pens Soil Data with Risk-Based Target Levels* (WA, 1999a). The statistical evaluation of WDPs soil analytical data is summarized in Table 6-23. Data collected during the 1994 investigation and the 1997/1998 investigation were included in the statistical evaluation and are discussed below.

The maximum reported activity of Ra-226 was detected in the 5.75 ft bgs sample from boring SBL-5 at 5.11 pCi/g. This sample was collected during the 1994 investigation from pen G-22 near the center of the WDPs (Figure 6-19). However, no subsurface samples collected during the

1997/1998 investigation, including one collected at the same location and depth as the SBL-5 sample, had Ra-226 activity greater than background. The maximum reported activity of Sr-90, 0.712 pCi/g, was detected in sample SSDP0263. This sample was collected from 25 ft bgs from pen G-22. The WDPs investigation data did not show any relationship of Sr-90 concentration with depth.

The maximum reported Hg concentration of 3.7 mg/kg was detected in surface soil in pen H-29. The investigation data showed that Hg concentrations attenuated sharply with depth. The maximum Cr-VI concentration of 1.02 mg/kg sample SSDP0285 was detected in surficial soil sample SSDP0285 from pen C-15. The investigation data did not show a relationship of Cr-VI concentration with depth. Surficial soil sample LEHR-SS-DP-141 from pen E-7 had the maximum detected concentration of alpha-plus-gamma chlordane at 2,186 µg/kg. Chlordane concentrations attenuated markedly with depth, and were below the detection limit in all of the soil samples collected from greater than two ft bgs.

Statistical evaluation of the WDPs soil data determined that the maximum concentrations or reasonable maximum exposure for all COCs are at or below the appropriate soil RASs, defined as the lowest appropriate RBAS or background for those COCs with background levels higher than the lowest RBAS (WA, 2001a). In addition, many of the WDPs soil sample locations were selected specifically to target areas with suspected elevated COC levels. Accordingly, use of these data in the statistical analysis and comparisons with RASs yields results that are more health-conservative than a random sample set.

The maximum reported concentrations of all constituents detected in the WDPs gravel and concrete curbing prior to the 2001 RA are presented in Table 6-24. The maximum reported Ra-226 and Sr-90 gravel concentrations of 1.94 pCi/g and 3.59 pCi/g, respectively, were detected in sample LEHRSSDP-0072, collected from pen C-32 (Figure 6-19). The concrete curbing sample with the maximum reported Ra-226 concentration of 3.67 pCi/g was also collected from pen C-32.

6.4.3 Removal Action Summary

In 1975, 64 pens (Rows A and B) were removed during construction of the Cellular Biology Laboratory (Figure 6-16). The barrels, fencing, concrete pedestals, gravel and interior curbing were removed, but the perimeter curbing was left in place. Figure 6-17 shows a schematic of a typical dog pen prior to demolition. In 1996, the barrels, interior chain-link fencing and concrete pedestals were removed from the remaining 256 WDPs. The barrels and concrete pedestals were properly packaged and shipped to the DOE Hanford site for disposal. In 1999 the interior chain-link fencing was released according to DOE Order 5400.5 and recycled off-site (EMS, 1999). These above-ground facility RAs are not considered part of the CERCLA RA, but are mentioned here for completeness.

Based on the statistical comparison of pre-RA soil data with RASs, no WDPs soil removal was necessary to reduce risk to acceptable levels. Because the analytical data for the gravel, asphalt and concrete curbs in the WDPs area were not sufficient to eliminate them as potential risks (WA, 2001d), the WDPs RA focused on removing these materials, as well as the metal grating underlying the gravel in many of the pens.

6.4.3.1 Removal Action Activities

Mobilization and site setup for the WDPs RA began on April 30, 2001. RA activities began in Aisle 3, the former storage location for chlordane-contaminated soil removed during the SWT area during a prior RA. As a conservative measure, the asphalt and 6 inches of underlying soil from Aisle 3 were removed, containerized in 19 Lift Liners and shipped to Envirocare of Utah for disposal.

Between May 22 and early August 2001, the concrete curbing, gravel, metal grating and fence posts were removed from the existing 256 WDPs. Approximately, 1,725 cu yd of gravel, 650 cu yd of asphalt, 800 cu yd of concrete curbing, and 45 cu yd of metal grating and fence posts were removed. This material was removed using an excavator, segregated into one of four waste streams and transported to the appropriate stockpile using a wheel loader. Following waste removal, confirmation samples were collected from the WDPs excavation area.

Gravel removed from each pen was placed into one of three piles based on data collected prior to the RA. All of the gravel was sifted to segregate the gravel from the soil. The soil was returned to WDPs excavation after on-site screening for Ra-226 and Sr-90 indicated that the concentrations were below the SC. All of the concrete curbing that was removed from the WDPs was pulverized with a universal processor and stockpiled.

The southern portion of the WDPs was then backfilled and compacted to grade, but the northern portion of the WDPs was left below grade. Currently, waste and material stockpiles are stored within the backfilled area of the WDPs. Five individual stockpiles containing gravel, concrete, metal and wood are located in above-grade cells, pending characterization sampling results.

6.4.3.2 Air Monitoring Results

Air monitoring was conducted in the WDPs before, during and after the RA. Statistical tests were conducted on these air monitoring data to determine if the concentrations of COCs in air were distinguishable from background or exceeded regulatory limits. Detailed descriptions of the sampling and analysis, statistical test methods and results are presented in Appendix D of this report. Statistical analysis of on-site air monitoring data collected during the WDPs RA indicated that ambient air concentrations did not exceed the background or applicable regulatory limits.

6.4.4 Post-Removal Action Contaminant Distribution

Based on the statistical evaluation of the WDPs soil data, all of the soil removed during the WDPs RA, with the exception of the Aisle 3 soil, was returned to the excavation following on-site screening for Ra-226 and Sr-90. After completion of the WDPs RA, confirmation samples were collected from the WDPs shallow soil and analyzed for Ra-226, Sr-90, chlordane, Hg and Cr-VI.

A total of 38 confirmation samples (including five field duplicates) were collected from the WDPs excavation. Both random-based and discretionary hot spot confirmation samples were collected to ensure attainment of RASs using a statistically-based sampling design. Twenty-one of

the primary sample locations were random-based and eight locations were discretionary (Figure 6-20).

Table 6-25 summarizes the WDPs confirmation sampling analytical results. Cr-VI concentrations exceeded the site-specific background concentration in 26 samples, but were well below the lowest RBAS, residential and industrial PRG. Hg and total chlordane were detected above background in some samples but were not detected at concentrations greater than any of the applicable standards. One alpha-plus-gamma chlordane result exceeded the RAS. Additional samples were collected surrounding the original sample location as discussed below. These data were included in the statistical analysis summarized in Table 6-25. All of the Ra-226 results were below site background concentration. Sr-90 was detected above background in 11 samples, but all concentrations were below the lowest RBAS.

The maximum reported Sr-90 activity, 0.491 pCi/g, was detected in soil sample SSWDC019, collected 1.5 ft bgs from pen I-28 (Figure 6-20). The maximum reported Hg concentration of 5.1 mg/kg was detected in soil sample SSWDC020, collected 1.5 ft bgs from pen I-22.

Rows C and D of the WDPs contain sub-grade gravel-filled trenches that are oriented in an east-west direction. The water lines contained within these trenches were removed during the 2001 RA. Five cobble samples (including one field duplicate) were collected during confirmation sampling. One cobble sample was collected from each of the four east-west running trenches at a discretionary location. The locations of cobble samples SSWDC021, SSWDC022, SSWDC025, SSWDC027 and SSWDC028 are shown on Figure 6-20. The maximum reported Ra-226 activity, 0.664 pCi/g, was detected in cobble sample SSWDC022, collected two ft bgs in pen D-22 (see Fig. 6-20). The soil beneath each of the cobble sample locations was also sampled and analyzed for the full confirmation suite. The maximum reported Cr-VI concentration of 1.17 mg/kg was detected in soil sample SSWDC026, collected beneath a cobble trench at 2.5 ft bgs in pen C-5.

As discussed above, Aisle 3 was the former storage location for chlordane-contaminated soil removed during the SWT RA. Four of the discretionary samples were collected from Aisle 3 to evaluate whether any residual chlordane remained (Figure 6-20). Surface soil samples were collected from four random locations and analyzed for chlordane only. Sample SSWDC033 had the maximum reported alpha-plus-gamma chlordane and total chlordane concentrations of 873 µg/kg and 2,120 µg/kg, respectively. This sample had the only alpha-plus-gamma chlordane concentration that exceeded the lowest (800 µg/kg) RBAS. Samples SSWDC023 and SSWDC029 had the second and third highest alpha-plus-gamma chlordane concentrations, at 333 µg/kg and 244 µg/kg, respectively. Samples SSWDC023 and SSWDC029 were both collected beneath the cobble trenches.

At the request of the RPMs, sample locations SSWDC033, SSWDC023 and SSWDC029 were re-sampled. Additional samples were also collected from the areas surrounding each sample location to determine the vertical and lateral extents of chlordane contamination (Figure 6-21). Sample SSWDC050 was collected from sample location SSWDC051, which had the maximum alpha-plus-gamma chlordane concentration of 1,529 µg/kg. Alpha-plus-gamma chlordane was not detected above the detection limit of 1.9 µg/kg in sample SSWDC050. However, sample SSWDC051, collected five ft north of sample SSWDC033 and SSWDC050, had an alpha-plus-

gamma chlordane concentration of 1,529 µg/kg and a total chlordane concentration of 4,340 µg/kg. All of the other samples collected around sample location SSWDC033 were well below the action levels.

The confirmation sample data are evaluated in detail in the *Draft Western Dog Pens Area Removal Action Confirmation Report* (WA, 2002c). This evaluation included a human health risk analysis based on the site-specific lowest RBAS. The human health risk analysis indicated that the RA activities reduced the cumulative cancer risk to a nominal range of 10^{-4} to 10^{-6} . Background comparisons (WRS and Quantile Tests) were conducted on the Ra-226 confirmation data set. Ra-226 was below background and therefore was not included in the human health risk analysis. The risk analysis determined that the cumulative non-cancer HQ was reduced below 1.0. All COCs passed the Hot Measurement Analysis.

6.4.5 Ground Water Impact Evaluation

During the 1998 WDP investigation, six grab ground water samples and one field duplicate were collected from borings drilled within the WDPs. Concentrations of all analytes in the ground water were similar to those detected recently in monitoring wells located upgradient of the WDPs Area, with the exception of nitrate in four of the seven grab ground water samples analyzed (WA, 1997e). The maximum detected nitrate concentration in the ground water samples was 78.6 mg/l, compared with the 25.4 mg/l typically detected in upgradient well, UCD1-18. There is no apparent correlation between the nitrate concentrations in ground water and those in immediately overlying soil (WA, 1997e). This suggests that nitrate from historic sources has already moved through the vadose zone.

As discussed in Section 6.4.4, chlordane in two samples was the only COC above its lowest RBAS in the WDPs confirmation samples (Table 6-25). Therefore, no post-RA DL sampling and vadose zone modeling was conducted for the WDPs. Vadose zone modeling was conducted earlier as part of the EE/CA for the WDPs and EDPs; however, Ra-226 and Cr-VI were not considered COCs at that time and were not included in the modeling. The other key COCs identified for the WDPs (Sr-90, Hg, and chlordane) were modeled and compared to the maximum WDPs soil concentration detected in all samples collected under CERCLA, including the confirmation samples. In addition, actual concentrations of each of the five WDPs COCs in ground water upgradient and downgradient of the WDPs were compared. Data from wells UCD1-20 and UCD1-24 (Figure 2-3) were used to represent ground water downgradient of the WDPs, and as described in Section 6.2.5, well UCD1-18 was used to represent upgradient or background conditions.

Ra-226 is periodically analyzed in upgradient well UCD1-18 and downgradient well UCD1-20. Ra-226 has ranged from 0.17 ± 0.13 to 2.31 ± 0.777 pCi/l in the downgradient wells and from 0.27 ± 0.15 to 1.34 ± 0.618 pCi/l in the background well. All these are below the 5 pCi/l Ra-226 MCL. Based on these results and the fact that the Ra-226 activity in all confirmation soil samples collected from the WDPs was below background, any impact to ground water by Ra-226 in WDPs soil is very unlikely.

Sr-90 was not detected in any of the ground water samples collected from downgradient wells UCD1-20 and UCD1-24 and background well UCD1-18 in the last six years. However, based on the vadose zone modeling results, it is very unlikely that the Sr-90 remaining in WDPs soil would have any measurable impact on ground water. As shown on Table 6-26, modeling results indicate that Sr-90 soil concentrations would have to be approximately 19 orders of magnitude greater than the maximum detected in WDPs area samples to result in ground water impact at the MCL.

Cr-VI concentrations in the two wells downgradient of the WDPs have ranged from 19 to 35 µg/l in well UCD1-20 and from 23 to 42 µg/l in well UCD1-24 since first sampled in winter 1995. These are similar to the background concentration of 39 µg/l for well UCD1-18, lower than Cr-VI concentrations in ground water under other portions of the Site, and below the 50 µg/l MCL for total chromium.

The maximum (5.1 mg/kg) soil confirmation sample result for Hg is above the modeled allowable soil concentration of 0.62 mg/kg for potential impact to ground water at the 2 µg/l MCL. However, the estimated time required for this impact to occur is almost 6,000 years. Over the last six years, Hg has not been detected with a detection limit of 0.2 µg/l in either of the downgradient wells or in the background well.

The maximum soil concentrations for alpha and gamma chlordane, 1,210 and 976 µg/kg, respectively, are many orders of magnitude below the model results of 59 mg/kg for gamma chlordane and 1.32E+4 mg/kg for alpha chlordane ground water impact at the 0.1 µg/l total chlordane MCL. Over the last six years, chlordane has not been detected in either of the downgradient wells with detection limits as low as 0.01µg/l.

Based on the soil concentrations, vadose zone modeling, and downgradient ground water concentrations, COCs in WDPs soil should not have any significant impact on ground water in the next several thousand years.

6.5 Eastern Dog Pens

6.5.1 Description and Operations

According to aerial photographs, Rows K and L of the EDPs (Figure 6-16) were constructed by May 1968. The final row of the EDPs (Row M) was completed by March 1970. Water lines in the EDPs were not bedded in gravel as some were in the WDPs. The EDPs were used to house beagles that were involved in the research through 1988 when research ceased. The EDPs operations were similar to those discussed in Section 6.4.1 for the WDPs.

6.5.2 Remedial Activity Summary

In 1996, the barrels, interior chain-link fencing and concrete pedestals were removed from the 96 EDPs. The barrels and concrete pedestals were properly packaged and shipped to the DOE Hanford site for disposal. In 1999 the interior chain-link fencing was released according to DOE Order 5400.5 and recycled off-site through an authorized release (WA, 2000a).

As discussed in Section 2.2.2, UC Davis and DOE are currently working on Draft MOA Amendment 1, which addresses the agreement for environmental restoration activities for the Landfill Disposal Unit 2/EDPs area. Therefore, no subsurface remedial actions have been performed to date.

Access to the EDPs will be controlled pending remediation of the underlying Landfill Disposal Unit 2. It is assumed that UC Davis will complete the landfill remediation prior to the end of 2004. In the interim, the following controls will be implemented until the signed date of the revised MOA:

1. Repair and maintain the perimeter fence to prevent public access to potentially impacted areas;
2. Affix permanent postings to the perimeter fence to prevent unsupervised gravel, asphalt or concrete disturbance; and,
3. Conduct semi-annual monitoring and inspections to determine the need for measures 1 and 2 above, and to verify that the EDP gravel, asphalt and concrete have not been disturbed.

Semi-annual inspections will be conducted to verify that the above controls remain in place until Landfill Disposal Unit 2 is remediated and a final solution meeting regulatory requirements is implemented. According to the MOA, UC Davis will also continue ground water monitoring in this area.

6.5.3 Contaminant Distribution

Table 6-27 summarizes investigations conducted in the EDPs. The nature and extent of contamination in the EDPs is based on the investigation conducted in 1999 and presented in the *Technical Memorandum: Investigative Results for the Former Eastern Dog Pens* (WA, 1999c). The 1990 and 1996 data were not collected under work plans that were prepared to CERCLA standards or approved by the LEHR RPMs. Therefore, these data were not included in the statistical evaluation of the EDPs soil. The EDPs soil analytical data from the 1999 investigation are summarized in Table 6-28. The EDP soil samples were collected from the upper two ft and do not include material from the landfill underneath the EDPs. The EDPs soil sample locations for all of the investigations are shown on Figure 6-22.

The 1999 EDPs investigation soil samples were analyzed for 58 constituents. Of these, only seven pesticides, and two PCBs were detected and only Sr-90, chromium, Cr-VI, were statistically above background. Dieldrin exceeded its site-specific lowest RBAS, residential PRG, and industrial PRG in one or more samples, and total chromium exceeded its residential PRG in two samples. Sr-90 was above the residential PRG, but below the site-specific lowest RBAS and industrial PRG. None of the other above-background COCs exceeded the RBAS or PRGs. Based on these data for the EDPs, all COCs in the upper three ft of soil above Landfill Unit 2 are statistically below their respective RASs (WA, 2001d).

Surficial soil sample SSDP0302, collected from pen M-8, had the maximum reported Ra-226 and Hg levels of 0.734 pCi/g and 14.6 mg/kg, respectively. Surficial soil sample SSDP0319, collected from pen K-1, had the maximum reported Sr-90 activity at 0.164 pCi/g. The maximum reported Cr-VI concentration of 0.673 mg/kg was detected in sample SSDP0320, collected from pen K-1 at 2 ft bgs. Sample SSDP0346, collected from surface soil in pen K-19, had the maximum detected concentration of alpha-plus-gamma chlordane (91.2 µg/kg). The maximum dieldrin concentration of 223 µg/kg was reported in surficial soil sample SSDP0338, collected from pen M-17.

The EDPs gravel and concrete curbing analytical results are summarized in Table 6-29. The EDPs gravel and concrete sample locations are shown on Figure 6-23.

6.5.4 Ground Water Impact Evaluation

Potential impact to ground water from COCs in EDPs soil above Landfill Unit 2 was evaluated by comparing results from the 1999 soil investigation with vadose zone modeling results. The presence of UC Davis Landfill Disposal Unit 2 under the EDPs limited the vertical extent of soil sampling in this area to the top two ft. Based on their presence above background levels in these shallow soils, vadose zone modeling was conducted for Sr-90, Cr-VI, Hg, and seven pesticides (Table 6-30). Ground water data from downgradient well UCD1-13 (Figure 2-3) were also compared to background ground water data from well UCD1-18.

The modeling results clearly indicate that ground water impact by Sr-90 in EDPs soil is very unlikely. As shown on Table 6-30, a soil concentration of 1.72×10^{15} pCi/g would be needed to result in ground water impact at the 8 µg/l MCL, and the maximum soil concentration detected was 0.164 pCi/g. This result indicating lack of ground water impact is corroborated by the Sr-90 results for well UCD1-13 (Table 6-19).

The DL modeling results indicate that Cr-VI in the EDPs soil should not impact ground water above background (Table 6-19). However, Cr-VI is consistently detected above the 39 µg/l ground water background level in downgradient well UCD1-13 at concentrations ranging from 61 to 94 µg/l. Although well UCD1-13 is immediately downgradient of the EDPs, it is also immediately downgradient of UC Davis Landfill Disposal Unit 2 and the disposal trenches. Based on the DL modeling results and the depth and nature of waste in the UC Davis Landfill and disposal trenches,

the Cr-VI detected in well UCD1-13 is probably the result of impact from these areas rather than from surface soil in the EDPs.

Based on the DL modeling, Hg in EDPs soil may impact ground water above the MCL; however, this would not occur for several thousand years (Table 6-30). Hg has not been detected in ground water from either background well UCD1-18 downgradient well UCD1-13 in the last six years.

The DL modeling results indicate that any impact to ground water from the seven pesticides detected in EDPs soil would be expected to be several orders of magnitude below the MCLs and would not occur for thousands of years (Table 6-30). None of these pesticides are detected in background well UCD1-18, and four of them (dichlorodiphenyl dichloroethane [DDD], dichlorodiphenyl dichloroethylene [DDE], dichlorodiphenyl trichloroethane [DDT] and PCB-1254) have never been detected in downgradient well UCD1-13. Alpha chlordane, gamma chlordane, and dieldrin are detected periodically in well UCD1-13 at concentrations up to 0.016, 0.0071 and 0.03 µg/l, respectively. As with Cr-VI, based on the DL modeling results and the depth and nature of waste in UC Davis Landfill Disposal Unit 2 and disposal trenches, the chlordane and dieldrin detected in well UCD1-13 may be the result of impact from these areas rather than from surface soil in the EDPs.

Based on the soil concentrations and vadose zone modeling, COCs in EDPs soil have not, and should not, have any significant impact on ground water.

6.6 Southwest Trenches

6.6.1 Description and Operations

Between the late 1950s and early 1970s, LEHR-generated LLW, fecal material, and laboratory wastes were reportedly disposed in shallow pits and trenches at the SWT area (Figure 1-2) (D&M, 1993). During that time period LEHR research focused on studying the health effects from chronic exposure to Ra-226 and Sr-90. Disposal practices consisted of excavating a trench and placing laboratory waste along with dog pen gravel and soil in the trenches. Laboratory waste consisted of syringes, vials, glass jars with unknown liquids and solids, animal bones, and other types of wastes. The trenches were then backfilled with the excavated native soil. In addition, part of the SWT area was used for treating dogs with chlordane for flea control. Specifically, a storage shed in the southwest corner of the SWT area apparently contained chlordane for treating dogs nearby (Figure 6-24).

6.6.2 Pre-Removal Action Contaminant Distribution

All pre-RA investigations in the SWT area are summarized in Table 6-31 and sample locations are shown on Figures 6-24 and 6-25. The maximum reported concentrations of all constituents detected in soil and waste above background at the SWT area prior to the 1998 RA are presented in Table 6-32.

The maximum reported pre-RA Ra-226 concentration of 7.06 pCi/g was detected in gravel sample LEHR-S-338 collected at 6.5 ft bgs. The highest reported pre-RA Ra-226 soil concentration was 3.94 pCi/g. The extent of the Ra-226 activity above background appeared to be confined to solid waste and soil within, and immediately below, the disposal trenches and pits (WA, 1998a).

The maximum reported pre-RA Sr-90 concentration of 16,700 pCi/g was detected in sludge sample LEHR-S-340, collected at a depth of 6.5 ft bgs. This sludge appeared localized and was removed and disposed off-site during the LFI. The highest pre-RA Sr-90 soil concentration was 22.3 pCi/g in sample LEHR-S-361 collected 14.5 ft bgs from beneath the largest disposal trench, T-6. Prior to the RA, the lateral extent of Sr-90 contamination in the SWT area did not appear to correlate with the waste disposal areas (WA, 1998a).

The maximum reported chlordane soil concentration from the LFI was 3.6 mg/kg (3,600 µg/kg) in LEHR-S-484, collected from a depth of 3.5 ft bgs in the southwest corner of the Site (the suspected chlordane application area as shown in Figure 6-25). Chlordane was detected at 2,000 mg/kg in this area in a previous investigation and was likely the result of a spill. However, shallow soil samples (LEHR-S-484, S-485, S-486) collected near the reported location of this sample contained far lower chlordane concentrations. No consistent pattern of vertical attenuation of chlordane in soil was observed (WA, 1998a).

The maximum reported pre-RA nitrate concentration of 390 mg/kg was detected in a soil sample LEHR-S-357, collected 14.4 ft bgs beneath Pit 2 (Figure 6-25). The pre-RA data suggested that the nitrate contamination was laterally confined to the area within and surrounding the disposal trenches and pits. The nitrate contamination did not appear to be vertically confined to the soil immediately beneath the waste trenches.

The maximum reported pre-RA Cr-VI concentration of 1.2 mg/kg was detected in a surface soil sample collected from boring SB-19 (Figure 6-24). The maximum reported pre-RA Hg concentration of 5.2 mg/kg was detected in soil sample LEHR-S-483, collected at three ft bgs along the southern edge of the SWT area (Figure 6-25). The pre-RA Cr-VI and Hg data did not show any obvious contaminant distribution trends. The maximum reported pre-RA Cs-137 activity of 23 pCi/g was detected in sample S-350 in Grid 7-9 at a depth of 0.5 ft bgs. This activity far exceeded all other investigative sample results and the sample location was removed during the LFI. Cs-137 appeared to be limited to surface soils and localized to the waste disposal trenches (WA, 1998e).

6.6.3 Removal Action Summary

6.6.3.1 Removal Action Activities

The SWT RA activities began in May 1998 and were completed by November 1998. The SWT RA was conducted in accordance with the *Final Work Plan for Removal Actions at Southwest Trenches, Ra/Sr Treatment Systems, and Domestic Septic System Areas* (WA, 2000c) and is discussed in greater detail in the *Final Southwest Trenches Area 1998 Removal Action Confirmation Report* (WA, 2001e).

The RA began in the southwest corner of the SWT area, where the chlordane contamination was identified. The driver COC for this portion of the RA was chlordane. In addition, as requested by the RPMs, the analytical program was expanded to include Ra-226, Cs-137, and Sr-90 (WA, 2001e). Following removal of the chlordane-impacted soil, soil and waste were removed from disposal cells in the SWT area. The driver COCs for this phase of the RA and their respective RASs were chlordane (800 µg/kg), Hg (0.63 mg/kg), Cr-VI (3.8 mg/kg), nitrate (36 mg/kg), Ra-226 (0.75 pCi/g) and Sr-90 (10 pCi/g). To allow for real-time decision-making and in consideration of cost and time, screening samples used to guide the RA were analyzed for chlordane, nitrate, Ra-226, and Sr-90, but not Hg and Cr-VI. Nitrate and Ra-226 were used as indicator compounds to represent the mobility of metals and to establish the lateral and vertical extent of contaminant migration.

Historical site information indicated that chlordane had been used at the Site for flea control and had been detected in the shallow soil in the southwest corner of the SWT area. Based on characterization sampling results, an excavation boundary was defined at the estimated RAS level around each "hot spot." An excavator removed contaminated soil to the limits shown in Figure 6-26. Excavated soil was placed in a front-end loader and transported to the WDPs aisles for stockpiling. A total of 450 cu yd of soil were shipped off-site for incineration and disposal at Safety Kleen of Utah.

Prior to the RA, the location and orientation of the buried waste disposal cells were not well known. Following removal of the chlordane-contaminated soil, two techniques were used to locate buried waste. First, a backhoe was used to trench along grid lines (Figure 6-26) throughout the SWT area. Then, a direct-push drilling rig was used to collect samples in the chlordane excavation area to define the lateral and vertical extent of two waste disposal cells.

In the northern excavation area (Figure 6-26), 217 cu yd of waste were removed from three trench-shaped disposal cells. Typical wastes in these trenches included gravel, syringes, and several glass jars.

A total of 466 cu yd of waste was removed from the western excavation area. The western excavations consisted of two parallel 10 to 12 ft deep trenches and a smaller shallow disposal pit. The waste in these trenches consisted predominantly of gravel mixed with glass jars, vials, syringes and other laboratory wastes. Several animal bones and a crushed 30-gallon drum were also removed from the western excavations.

In the southern excavation area, a total of 190 cu yd of waste were removed during the RA. Waste in this area was not commingled with gravel; instead, isolated pockets of labware-dominated waste in a soil matrix were discovered. For example, in the upper two ft, waste items consisted of trash such as cans, plastic bags, and Styrofoam cups. However, a deeper layer of soil with vials, glass jars containing unknown liquids and solids, and bones was also observed. Following completion of the waste removal activities and confirmation sampling, the SWT area was backfilled and compacted to grade with clean fill.

6.6.3.2 Air Monitoring Results

Air monitoring was conducted in the SWT area before, during and after the RA. Statistical tests were run on these air monitoring data to determine if COC concentrations in air were distinguishable from background or exceeded regulatory limits. A detailed description of the sampling and analysis, statistical test methods and results are presented in Appendix D of this report. Statistical analysis of on-site air monitoring data collected during the SWT RA indicates that ambient air concentrations did not exceed background or applicable regulatory standards.

6.6.4 Post-Removal Action Contaminant Distribution

In the northeastern portion of the SWT, a near-surface layer of gravel approximately 18 inches deep was observed. Subsurface cobble trenches were also noted in the eastern portion of the site. The cobbles measured two to three inches in diameter and appeared to represent a drainage structure. The top of the cobble trench was approximately 18 inches bgs and measured 1 to 2 ft in width and depth. Since no waste items had been noted in this area and the field instrumentation did not indicate the presence of contaminants, these features were not removed (WA, 2001e). Rather, a sampling plan was prepared to characterize the cobble features and the soil beneath. Eighteen soil samples were collected beneath the cobbles and gravel (Figure 6-27). In addition, 10 cobble samples and one field duplicate were collected. Soil samples were collected six inches into the native soil at depths ranging from 2.0 ft bgs to 4.5 ft bgs. Cobbles were selected from depths of 1.5 to 3 ft either randomly or based on visual observation and sent to an off-site laboratory for preparation, which included shaving and grinding the surface of the cobble and analyzing the removed material.

Table 6-33 presents the soil analytical results for the driver COCs. The 18 soil samples were also analyzed on-site for Ra-226 and Sr-90. None of the 18 soil samples analyzed for nitrate, Cr-VI, Hg, Ra-226, Sr-90 and chlordane contained concentrations greater than the RASs. Hg was detected above the RAS of 3.1 mg/kg in 1 soil sample, at a maximum concentration of 3.23 mg/kg. This RAS of 3.1 mg/kg is higher than the 0.63 mg/kg RAS (background level) used during the RA because the Hg RBAS for SWT area was recalculated as part of the *Final Southwest Trenches Area 1998 Removal Action Confirmation Report* (WA, 2001e). This Hg RBAS was recalculated because speciation analyses indicate that Hg in LEHR soil is >99% mercuric sulfide, which is significantly less mobile and less toxic than the forms of Hg assumed in the original RBAS (WA, 2001e).

Cobble samples were analyzed at an off-site laboratory for driver COCs, gross alpha/beta and gamma spectrometry using standard US EPA methods. Table 6-33 presents the cobble sampling

analytical results for the driver COCs. None of the 11 cobble samples analyzed for nitrate, Cr-VI, Ra-226 and Sr-90 contained concentrations greater than the RASs. Chlordane was detected above the 800 µg/kg RAS in one duplicate sample at a concentration of 3,590 µg/kg.

Following the removal of chlordane-impacted soil, a total of 19 confirmation samples (including two field duplicates) were collected from the chlordane excavation. The objective of this sampling was to ensure attainment of the chlordane cleanup goal using a statistically-based sampling design (WA, 2001e). The confirmation samples were collected at depths ranging from 0.5 to 4 ft bgs and were analyzed for pesticides/PCBs. The chlordane excavation confirmation sample locations are shown on Figure 6-28 and the analytical results are summarized on Table 6-34. Gamma chlordane, heptachlor, and heptachlor epoxide were the only constituents detected above the reporting limit. Heptachlor epoxide at 3.8 µg/kg was the only constituent detected above the RAS.

A total of 70 confirmation samples (including seven field duplicates) were collected from the northern, western and southern excavations at depths ranging from 2 to 13 ft bgs (Figure 6-29). All of the samples were analyzed for a full suite of COCs and the analytical results are summarized in Table 6-35. Of the 178 analytes, 28 were detected above background concentrations in one or more samples. Of those analytes statistically above background, only Hg in one or more samples was above its lowest RBAS, iron and K-40 were above background and the residential PRG; K-40 was the only constituent above background in the statistical tests and the industrial PRGs.

The maximum Ra-226 concentration of 0.76 pCi/g was detected in sample SSTC046 collected 12 ft bgs. The maximum Sr-90 concentration of 7.91 pCi/g was detected in sample SSDTC020, collected at three ft bgs from the southern side wall of the southern excavation area. The maximum reported Hg concentration of 6.1 mg/kg was detected in sample SSTC069, collected four ft bgs from the eastern side wall of the northern excavation area. The maximum reported Cr-VI concentration of 1.06 mg/kg was detected in sample SSDTC052, collected four ft bgs from the western side wall of trench W-10 (Figure 6-29). The maximum reported alpha and gamma chlordane concentrations at 110 and 94.8 µg/kg, respectively, were detected in sample SSDTC058DL1, collected four ft bgs from the northern excavation area.

The confirmation sample data indicate that all chlordane, Sr-90 and Cr-VI contamination above the RASs has been removed. Sample SSTC046 was the only sample with a Ra-226 concentration above the RAS. This sample was only 0.01 pCi/g above the 0.75 pCi/g Ra-226 RAS. Therefore, the confirmation data suggest that the Ra-226 contamination has been removed.

The confirmation sample data are evaluated in detail in the *Final Southwest Trenches Area 1998 Removal Action Confirmation Report* (WA, 2001e). This evaluation included a human health risk analysis based on the site-specific lowest RBAS and a DL analysis. Background comparisons (WRS and Quantile Tests) were conducted on the antimony, barium, copper, Pb, manganese, Ra-226, Th-228, and, Th-232 confirmation data sets. All of these constituents passed their respective background comparisons and were removed from the human health risk analysis. The human health risk analysis indicated that the RA activities reduced the cumulative cancer risk to a nominal range of 10^{-4} to 10^{-6} . The risk analysis determined that the cumulative non-cancer HQ was reduced below 1.0.

A Hot Measurement Analysis was also conducted on the SWT confirmation data. One Cs-137 detection exceeded the Hot Measurement Upper Limit.

The preliminary DL analysis determined that nitrate, Hg, C-14, Cs-137 and tritium should be retained as DL COCs. Nitrate was detected above the detection limit in 40 confirmation samples, 18 of which were above the RAS. Confirmation sample SSDTC082 had the maximum nitrate concentration of 909 mg/kg. This sample was collected at a depth of 12 ft bgs in the western excavation area. Additional nitrate delineation sampling was performed to define its vertical and lateral extents. Nitrate concentrations decreased with increasing depth, with the maximum detected values found at 10 to 15 ft bgs. Based on this investigation, the mass of nitrate in soil above the background level of 36 mg/kg in the SWT area was calculated as 950 pounds (WA, 2001e). The nitrate concentration contours in the 12 to 15 ft depth interval and the vertical nitrate distribution in the SWT area are shown on Figures 6-30 and 6-31, respectively.

Two confirmation samples had Hg concentrations greater than the 3.1 mg/kg RAS. Confirmation sample SSDTC069 had the maximum Hg concentration of 6.1 mg/kg. This sample was collected at four ft bgs in the northern excavation area.

As described in the *Designated-Level Sampling and Analysis Plan for the Southwest Trenches* (WA, 1999b), six soil borings were drilled and sampled in the SWT area to provide additional information on the vertical distribution of Cs-137, C-14, and tritium in soil. The two locations with the highest and second highest activities for each of these three constituents, as indicated by the confirmation sample analytical data, were selected for drilling (Figure 6-32). Samples were collected every five ft, starting at ten ft bgs. The deepest samples collected for tritium and Cs-137 analysis were from 30 ft bgs, and the deepest samples collected for C-14 analysis were at 45 ft bgs.

The analytical results for these samples are presented in Table 6-36. Tritium results were below the LEHR background level of 1.2 pCi/g in all samples from both borings, with no obvious activity trend with depth. C-14 activities in boring DL-3 were above the LEHR background level of 0.13 pCi/g at all depths, with a generally decreasing activity trend with depth. This boring is located in the UC Davis trench disposal area instead of the SWT area (Figure 6-32). The UC Davis trench disposal area is believed to extend into and across the southern boundary of the SWT area. In boring DL-4, the sample from 10 ft bgs had a C-14 activity of 0.352 pCi/g. All deeper samples had lower C-14 activities that showed no trend with depth and were near or below the background activity. All Cs-137 activities at all depths in both DL borings were below the 0.012 pCi/g background level.

The data collected during the DL sampling were used in vadose zone modeling to determine the potential adverse impacts to ground water at the Site. In response to RPM comments on the Draft RI, a follow-up DL analysis and vadose zone modeling were conducted using all validated data with accurate x,y,z coordinates that represent remaining (i.e., not excavated) material (see Section 4.3). All of these modeling results are discussed below.

6.6.5 Ground Water Impact Evaluation

As described above, the SWT area COCs identified from the confirmation data DL screening that could potentially impact ground water are Cs-137, C-14, tritium, Hg, and nitrate. Additional COCs identified through a second round of DL screening that considered all data that represent remaining (i.e., not excavated) material include Am-241, Sr-90, Cr-VI and zinc. DL modeling was conducted for these COCs, and the results were compared to actual soil sampling results. In addition, actual impact to ground water was assessed by comparing concentrations in SWT area well UCD1-4 and nearby downgradient well UCD1-23 (Figure 2-3) with background water concentrations from UCD1-18. Results of this evaluation are presented in Table 6-37.

As discussed in Section 6.6.4, above-background C-14 soil activity may extend to the water table (as assumed in the DL modeling) in only one isolated area near boring DL-3. As noted above, this boring is located in the UC Davis trench disposal area instead of the SWT area, and therefore the contamination is probably not DOE's responsibility. Because C-14 soil activity in excess of background was detected at all depths to the water table in this boring, it appears likely that C-14 in soil in this area has impacted, or will impact, ground water above background levels. Because C-14 soil activity in six of the nine samples from DL-3 also exceeded the 0.292 pCi/g modeling result for MCL impact, local ground water impact may also exceed the MCL. However, because these above-background C-14 activities appear to be limited to a very small area and the DL modeling is very conservative, this potential ground water impact is likely insignificant. This conclusion is supported by the C-14 activity measured in ground water from downgradient well UCD1-23, which was approximately an order of magnitude less than the 2,000 pCi/l MCL in samples collected prior to the RA in 1998. Since the RA in 1998, C-14 activities in this well have decreased below the 20 pCi/l detection limit.

The DL modeling results for Cs-137, Am-241, and Sr-90 indicate that their presence in low activities in SWT soil presents no significant risk to ground water (Table 6-37). The modeling results indicate that activities at least two orders of magnitude higher than the maxima detected in SWT soil would be needed to impact ground water above background, and significantly higher concentrations would be needed to impact above MCLs. Ground water data from nearby wells UCD1-4 and UCD1-23 confirm the lack of impact by these COCs.

The maximum tritium activity detected in SWT confirmation soil samples was 5.2 pCi/g, and the RME activity was 0.76 pCi/g. The tritium activities detected in all soil samples from the two DL borings were lower than both the LEHR background level of 1.20 pCi/g and this RME activity. Based on the DL modeling results (Table 6-37), it appears that tritium in SWT area soil would have very limited impact on ground water beyond that due to background soil, and that any impact likely would be well below the 20,000 pCi/l MCL. Ground water samples from SWT area well UCD1-4 and downgradient well UCD1-23 have not been analyzed for tritium in the last six years.

The DL modeling results indicate that nitrate remaining in SWT area soil could impact ground water above the 10 mg/l nitrate (as nitrogen) MCL and 25 mg/l background level (Table 6-37). However, nitrate in wells within and just downgradient of the SWT area show nitrate levels ranging from 1.3 to 11 mg/l, lower than the 25 mg/l background. To put into perspective the

potential additional impact to ground water represented by nitrate above background in the SWT area soil, the mass of this nitrate was calculated as 950 pounds (Section 6.6.4). The mass of nitrate in one acre of vadose zone (assumed to be 20 ft thick) at the average background concentration of 12.4 mg/kg is approximately 1,100 pounds (WA, 2001e). Agriculture in the UC Davis area discharges an estimated 17,000 pounds of nitrate (as nitrogen) per year to ground water, and the UC Davis outfall has historically discharged 36,500 pounds of nitrate as nitrogen per year to Putah Creek (D&M, 1990b). Therefore, the potential impact to ground water from nitrate remaining in SWT soil is not significant compared to these regional nitrate impacts.

The DL modeling results indicate that Hg remaining in SWT area soil could impact ground water above background, and could potentially result in a localized impact above the MCL. However, the time until peak impact is approximately 5,000 years (Table 6-37). Although Hg was detected at 0.61 µg/l in downgradient well UCD1-23 in 1995, it has not been detected above the detection limit (<0.20 µg/l) since then. Hg has never been detected in upgradient well UCD1-18.

The DL modeling indicates that localized zinc remaining in SWT soil could potentially impact ground water above background, and that Cr-VI could potentially impact local ground water slightly above background and the MCL (Table 6-37). However, actual ground water data from wells UCD1-4 and UCD1-23 do not show above-background impact by either of these COCs.

Based on all data representative of soil remaining in the SWT area and DL modeling results, tritium, nitrate, Cr-VI, and zinc may impact local ground water above background within the next several thousand years. Nitrate and Cr-VI may also impact local ground water above the MCL. However, based on actual ground water data from the SWT area, there is no evidence of above-background impact to ground water by any of these COCs (Table 6-37).

6.7 DOE Box

6.7.1 Description and Operations

Approximately 55 cu yd of LLW were disposed in a 36 ft by 9 ft by 10 ft on-site trench known as the DOE Box (Figure 1-2). The DOE Box was a repository used by the LEHR facility for disposal of miscellaneous LLW associated with research including syringes, bottles, vials and gravel. The DOE Box Investigations are presented in Table 6-38.

6.7.2 Removal Action Summary

In 1996, a time-critical RA was conducted at the DOE Box area through a CERCLA time-critical RA memorandum (DOE/OAK, 1996). A backhoe was used to excavate a series of trenches to determine the location of the DOE Box. The trenching activities did not find any evidence of an actual box buried beneath the surface, but did locate gravel and labware in an area where such items

were thought to have been disposed. The excavation at the DOE Box area was approximately 40 ft by 12 ft by 10 ft deep. The waste matrix was encountered two to three ft bgs, beneath a layer of gravel/soil overburden. Deteriorated plywood was found over and on the sides of the trench.

During the 1996 time-critical RA, approximately 110 cu yd of waste were removed from the DOE Box area. This waste was containerized in 33 B-25 boxes. The waste matrix included soil, gravel, steel runway matting, plywood, syringes, bottles and vials. Seventy-two bottles containing between two ounces and one gallon of unidentified fluids were recovered from the north end of the excavation. Although most of these bottles appeared to be intact, 11 bottles showed signs of leakage. Following removal of the waste matrix, the area was over-excavated to remove approximately six inches of native soil from the excavation bottom and side walls. Waste characterization sample analytical results collected from the waste matrix during the RA are summarized in Table 6-39. Nine soil samples were then collected from the native soil along the excavation side walls and bottom. The excavation was lined with a 20-mil high density polyethylene liner and backfilled with clean fill. The DOE Box area waste was shipped to the DOE Hanford site for disposal.

6.7.3 Post-Removal Action Contaminant Distribution

Following the 1996 time-critical RA, confirmation samples were collected from the excavation. The majority of the confirmation sample radionuclide concentrations were below their respective minimum detectable activities. There were no radionuclides detected at concentrations significantly above their respective background and/or lowest RBAS values. However, the confirmation sampling plan design was not statistically-based and the confirmation samples were analyzed for a limited suite of analytes. The *Sampling and Analysis Plan for the DOE Disposal Box Area Confirmation Data Gaps at the Laboratory for Energy-Related Health Research* (WA, 2001f) was designed to obtain sufficient data for proper closure of the DOE Box area. The additional sampling was conducted in the spring of 2002. The analytical results from this sampling event are discussed below.

Thirty samples and three field duplicates were collected from the DOE Box area during the closure sampling. Nine soil samples were analyzed for a full suite of parameters and 21 were analyzed for a limited suite including cadmium, total chromium, Cr-VI, Hg and nitrate. The confirmation sample locations are shown on Figure 6-33. Of the 189 analytes, 15 were detected above their respective background concentration in one or more samples. Of those analytes statistically above background, only Hg was above its lowest RBAS concentration; no constituents were above their respective residential or industrial soil PRGs. The closure sample analytical results for samples with concentrations above background, PRGs and/or RBAS are summarized in Table 6-40.

Eleven Hg results ranging from 0.25 to 3.9 mg/kg exceeded both background and the lowest RBAS. The maximum reported Hg concentration, 3.9 mg/kg, was detected in sample SSDBC006, which was collected 4.4 ft bgs from the eastern sidewall. All of the Cr-VI results from the closure sampling were above the background concentration of 0.054 mg/kg, but below the lowest RBAS of 3.8 mg/kg.

A human health risk analysis and DL analysis were conducted on the DOE Box closure sample results and are discussed in detail in Appendix F. Background Comparisons (WRS and Quantile Tests) were conducted on barium, copper, Pb, manganese, Hg and Th-232 closure sampling data sets. All of these constituents passed their respective background comparisons and were removed from the human health risk analysis. The human health risk analysis indicated that the cumulative cancer risk at the DOE Box area is below 10^{-6} for Exposure Scenarios 1 and 2. The cumulative cancer risk for Scenario 2 is below 10^{-5} . The risk analysis also determined that the cumulative non-cancer RBAS HQ was 4.30 for the DOE Box Area, with Hg contributing 3.95 to this cumulative ratio. Hg was the only COC that failed a Hot Measurement Analysis of the contamination data.

The preliminary DOE Box Area DL analysis identified that Cr-VI, Hg, molybdenum, and U-235/236 required additional evaluation (WA, 2002d) for potential ground water impact. In October 2002, DL samples were collected from the DOE Box area. Samples were collected from DL boring DB-DL1 (Figure 6-33) at the location of sample SSDBC009/010 and analyzed for Hg, molybdenum and Cr-VI. Sample SSDBC009/010 had the second highest Hg concentration in the DOE Disposal Box Area, 2.6 mg/kg, and the third highest Cr-VI concentration, 0.446 mg/kg. No molybdenum data were collected from this location; however, the second highest molybdenum concentration, 0.53 mg/kg, was detected in a sample collected approximately five ft north of sample location SSDBC009/010. The Hg, molybdenum and Cr-VI data show no concentration distribution trends that indicate a release of contamination. Therefore, sampling for these metals from one boring location was justified. Sample SSDBC035 had the highest U-235/236 concentration 0.074 pCi/g. Therefore, DL boring, DB-DL2 (Figure 6-33) was drilled at this sample location. Soil samples were collected from each DL boring at five-ft intervals for DL COCs, with the first sample collected approximately five ft below the original sample depth of 5.5 ft bgs. Samples were collected to 35 and 35.5 ft bgs for DL borings DB-DL 1 and DB-DL 2, respectively.

Ground water samples were collected from borings DB-DL1 and DB-DL2 when ground water was encountered at 50 and 49 ft bgs, respectively. The ground water samples were analyzed for metals, radionuclides, SVOC, SVOCs, pesticides, nitrate, and Cr-VI. In addition, the first two soil samples collected from boring DB-DL1 were analyzed for Hg, molybdenum and Cr-VI using the DI WET procedure.

DL boring soil results are presented in Table 6-41. All DL boring Hg results were below the background level and all molybdenum results were below the detection limit. All DL boring samples except the deepest, 35-ft bgs sample had above-background Cr-VI concentrations, and all samples contained above-background U-235/236 concentrations. The maximum Cr-VI concentration was 0.244 mg/kg at 25 ft bgs (background is 0.054 mg/kg) and the maximum U-235/236 concentration was 0.0671 pCi/g at 25.5 ft bgs (background is 0.038 pCi/g). None of the DL analytes showed a concentration trend with depth.

6.7.4 Ground Water Impacts

DI WET results for DOE Box soil samples from boring DB-DL1 are shown in Table J-11 of Appendix J. The DI WET results were directly compared to three water quality goals (background, MCLs, and tap water PRGs) to determine the soil's potential to degrade water quality. As described in Section 6.3.2.2, this assumes an attenuation factor of ten.

The DI WET results were first compared to background. The maximum detected concentration of each constituent detected in HSU 1 ground water well UCD1-18, located upgradient of the LEHR site, was used as the background concentration. None of the detected COCs were above background. Therefore, no additional evaluation of the DI WET results was needed.

A ground water sample was collected from the two DL borings in the DOE Box area (Figure 6-33). Table J-12 of Appendix J presents the analytical results for this sample that were above detection limits. The ground water samples were compared to background, MCLs and PRGs. Twenty-four of 33 COCs were detected above their respective background levels in one or more samples. Of these, barium, manganese, Hg, nickel, thallium, actinium-228, bismuth-212 (Bi-212), Pb-212, Pb-214, and K-40 were above their respective MCL and/or PRG. One COC without an established background level, gross alpha, also was detected above its MCL. The ground water samples from the DOE Box area were collected from a borehole, not from a properly completed ground water well. The sample contained sediment soil particles and was not filtered in the field or in the laboratory. Therefore, these ground water results represent overestimates of the actual ground water concentrations in this area.

DOE Box soil sampling data indicate that Cr-VI, Hg, molybdenum, and U-235/236 were present above background and therefore required modeling to further assess potential ground water impact. DL modeling results (Table 6-42) indicate that the residual Cr-VI and U-235/236 in soil in the DOE Box area will not impact ground water above the background level or MCL. Although above-background concentrations of Cr-VI are detected in the nearest downgradient well (UCD1-12), this well is over 400 ft from the DOE Box and ground water in this area is known to be impacted by other sources.

The modeling results indicate that Hg and molybdenum remaining in DOE Box area soil might impact ground water above background, and that Hg may also impact local ground water above its MCL. However, modeling indicates that the peak concentrations for Hg and molybdenum will not occur for 3,840 and 1,488 years, respectively. (Table 6-42). Hg and molybdenum concentrations in the nearest downgradient well are at or below background levels.

In summary, DOE Box soil results, DL modeling, and DI WET analyses suggest that any COCs remaining in the DOE Box area soil are unlikely to impact ground water above background for at least the next 1,000 years.

6.8 Storm Water, Surface Water and Sediment Investigations

6.8.1 Storm Water Monitoring

As discussed in Section 2.3.4.1, storm water samples are collected from LS-1, located on the west side of the Site, which pumps runoff from much of the western part of the Site (Figure 2-4). LS-1 pumps water into the drainage ditch along the eastern edge of Old Davis Road, and the water then flows through one of two culverts that run under Old Davis Road. The drainage ditch on the west side of Old Davis Road is graded so that the storm water flows south toward Putah Creek.

Currently there is no flow meter at LS-1 or at the location where water from LS-1 discharges to the creek, and the volume of storm water runoff from the LEHR Federal Facility that actually discharges to Putah Creek has not been gauged. Because of this, it is difficult to assess the actual impact that COCs in storm water runoff from the LEHR Federal Facility may have on the creek. Much of the storm water may infiltrate prior to reaching Putah Creek. However, to be conservative, the storm water runoff data are compared directly to aquatic life protective criteria and MCLs. The aquatic life protective criteria discussed below are the lowest fresh water criteria from a compilation of US EPA and California criteria in *Application of Risk-Based Screening Levels and Decision Making to Sites with Impacted Soil and Groundwater* (CRWQCB, 2000).

Between 1997 and January 2001, antimony, barium, copper, dieldrin, heptachlor, Pb, Hg, molybdenum, zinc and 4,4'-DDT were detected above the lowest aquatic life protection criteria in one or more samples of LEHR Federal Facility storm water. All of the metals detected are naturally occurring and may not be associated with DOE-funded LEHR research. Similarly, there are potential pesticide sources (agricultural and sanitary waste water) other than those related to the LEHR Federal Facility. In January and November 2001, the storm water samples collected from LS-1 were analyzed for "low-level" analysis by EPA Method 1631. The Hg concentrations from the January and November samples were 0.264 µg/l and 0.540 µg/l, respectively. Both of these concentrations exceed the lowest aquatic life protection criterion for Hg of 0.012 µg/l.

Between 1996 and January 2001, the driver COCs for all of the RAs at the LEHR Federal Facility were not detected in storm water samples collected from LS-1 at concentrations that exceed their respective MCLs. The naturally occurring metals antimony, chromium, iron, Pb, manganese and nickel were detected at concentrations exceeding their respective MCLs at one or more locations in the winter 1996 and spring 1997 samplings. However, these samples were not filtered prior to field preservation, resulting in dissolution of suspended materials and anomalously high concentrations of some metals. In 2000, antimony was detected at concentrations up to 22.6 mg/l in LS-1, exceeding the 6 mg/l MCL. The antimony concentration are consistent with previous years (WA, 2001j). No other constituents have been detected at concentrations above their respective MCLs in storm water samples collected from LS-1 between 1996 and January 2001.

6.8.2 *Putah Creek Investigations*

As indicated in Section 2.3.4, surface water, storm water and limited sediment/biota sampling have been conducted for several years to determine if the activities at the LEHR Site have impacted Putah Creek.

A study completed on the sediments, water and fish in 1996 by ATSDR found that the:

- Sediments, in general, did not contain elevated radionuclide, metal or organic concentrations compared to background, except for one area with elevated Hg in the sediments;
- Creek water did not contain elevated radionuclide, metal or organic concentrations compared to background; and,
- Fish had elevated concentrations of Hg-203, Hg, and Pb.

One area with elevated Hg in the sediments could be the source of Hg in the fish. The potential dose of radiation from Hg-203 by eating the fish from Putah Creek does not present a health hazard. However, the potential doses of Hg and Pb by eating fish from Putah Creek does pose a possible health hazard (ATSDR, 1997). Conclusions about the source or sources of Hg and Pb were not drawn from the ATSDR study.

Hg-203 is not currently analyzed in samples collected from either storm water or surface water. Hg has been detected up to 0.540 µg/l and Pb has been detected up to 3.5 µg/l in storm water collected from LS-1, but it is not clear whether these metals result from LEHR Federal Facility activities or are naturally occurring.

6.8.3 *Off-Site Cesium-137 Investigation*

As discussed in Section 2.3.4.3, an off-site Cs-137 investigation was conducted in 1998 because Cs-137 was detected in 1996 and 1997 investigations at levels that equal or exceed the lowest RBAS in surficial soil samples collected from a drainage ditch on the western side of LEHR. The 1996-7 investigations were conducted because of concern that overflows from the Ra-226 Treatment System may have impacted shallow soil in the drainage area.

The 1998 investigation, which included a surface gamma radiation survey and laboratory analysis of 47 soil samples, indicated that:

- Cs-137 concentrations detected in samples collected from the drainage ditch were within the range reported by others for activities associated with global fallout from atmospheric nuclear testing for this area;
- Cs-137 activities measured in areas of the drainage ditch potentially impacted by Ra-226 treatment system overflows are comparable to those measured in the distant (background) storm water runoff ditch; and,

- Potential human health risks from the Cs-137 found in the ditch appear to fall within the 10^{-4} to 10^{-6} excess upper bound lifetime cancer risk range (WA, 1999f).

Therefore, no further investigation of Cs-137 is warranted.

6.9 Air Monitoring

Air sampling is not required under the Site Environmental Monitoring and Surveillance Plan (EMO, 1992) since LEHR does not have any active air effluent discharges from DOE-funded research activities. However, a year-long baseline air monitoring program was implemented by PNNL in August 1995, primarily to meet CERCLA requirements and to support an accurate and complete risk assessment for the LEHR Site.

The results of the baseline air monitoring program indicate that concentrations in air of the measured radionuclides, metals, VOCs, and chlordane are similar to those at the background locations (Figure 2-5), and that all levels are well below DOE and/or US EPA standards (PNNL, 1996a). Following the baseline study, PNNL conducted bi-monthly monitoring for gross alpha and beta. WA continued the bi-monthly monitoring after assuming the air monitoring responsibilities in early 1997. In June 1998, WA modified the air sampling program to monitor for potential COC releases into ambient air as a result of RA activities.

RAs were conducted at the LEHR Federal Facility in 1998, 1999, 2000 and 2001 at the SWT Area, Ra/Sr Treatment Systems Area I, the Ra/Sr Treatment Systems Area II and WDPs, respectively. The RA air monitoring program consisted of air sampling before, during and after each RA. Following the SWT RA, air monitoring was no longer conducted during non-RA time periods. The RA air monitoring program included a baseline sample collected prior to each RA, monthly sampling during the RA, and a follow-up sampling event after the RAs were completed. The analytical suite for the RA air monitoring program was based on the soil COCs in each RA area. AML-7, the mobile air monitoring station, was moved prior to each RA to an area downwind of each RA (Figure 2-5).

The overall reduction in air monitoring is justified for the following reasons:

- There are no longer any point sources of radionuclide emissions at the LEHR Federal Facility.
- The only potential radionuclide air emission sources at the LEHR Federal Facility in 1998 were limited to four areas of potential windblown, fugitive dust emissions: the SWT area; the Ra/Sr Treatment Systems area; the EDPs area, and the WDPs area. Fugitive dust emissions have the greatest potential for increasing during RA events that include excavation and movement of soil in one of these four areas.

- The air monitoring data for the last three years indicate that there is no significant variance of radionuclide air emissions.
- The reduction of air monitoring reduced laboratory, operation, and personnel costs for the LEHR Federal Facility air monitoring program.
- There is no regulatory driver requiring more frequent air monitoring.

The air monitoring data collected during each RA and the validated data from the site air monitoring were statistically evaluated using the WRS and Sign Tests. The results of these statistical tests are presented in Appendix D, and are summarized by RA area in Sections 6.2.3.2, 6.3.4.3, 6.3.7.3, 6.4.3.2, and 6.6.3.2. In addition, the National Emissions Standards for Hazardous Air Pollutants for Emissions (NESHAP) of Radionuclides Report is submitted annually to the U.S. EPA by June 30 of each year in accordance with U.S. EPA regulations. This report summarizes calculated annual airborne radiological emissions from the Site. In summary, the air monitoring data indicate that on-site air concentrations before, during and after all RAs were statistically the same as off-site air concentrations.

6.10 Environmental Radiation Dose Monitoring

The LEHR Federal Facility ambient radiation monitoring program uses TLDs to monitor gamma radiation throughout LEHR. The TLDs have been placed near perimeter fence lines, radioactive waste storage areas, and various work areas around LEHR. The locations of the some of the TLDs have been modified each year based on RA activities and waste storage locations. The TLDs are collected quarterly and an annual gamma radiation dose is calculated for each location. TLD detectors are analyzed by Radiation Detection Company, which is certified by the National Voluntary Laboratory Accreditation Program. The laboratory data are normalized for each quarter by subtracting site background activity from each location. TLD 35, located at the equine to the north of LEHR (Figure 2-7) is used to monitor background. The TLD data are reported each year in the ASER, which is provided to regulators, community groups, and other interested parties.

The average annual background dose near LEHR, as measured by TLD 35, for 1998 through 2000 has been 86 millirem per year (mrem/yr). The annual dose at LEHR exceeded this background dose in 1998 near the Imhoff area where the dose was 104 mrem/yr and in 1999 near the DOE radioactive sources stored in Geriatrics-I where the dose was 90 mrem/yr). Both locations were controlled areas to which public access is prohibited. All doses measured in 2000 were at or below background.

The DOE public dose limit for exposure of members of the public as a consequence of routine DOE activities is 100 mrem/yr above background. The TLD monitoring results show that ambient radiation detected at LEHR is not elevated with respect to off-site background, and is well below the DOE dose limit for the general public.

Table 6-1. Evaluation of LEHR Federal Facility Areas as Potential Contaminant Sources

LEHR Federal Facility Area ⁽¹⁾	Surface Area (sq ft)	Potential as Contaminant Source	Response Activities To Date	Investigation Data Adequacy
Co-60 Irradiation Field	N/A	Not a potential source to the environment based on area use (i.e., dogs removed immediately after irradiation).	Co-60 source removed and shipped off site (Section 2.4.3).	Not applicable.
Imhoff Storage Tanks, Sr-90 and Ra-226 Leach Fields, Sr-90 and Ra-226 Waste Tanks (collectively referred to as Ra/Sr Treatment Systems)	6,455	Potential source based on use for treatment of radioactive animal waste.	Non-time-critical removal action conducted in 1999 and 2000 (Section 6.2.3).	Data adequate for risk assessment.
Dry Wells A through E (DSS 1/5)	97.5	Potential sources based on possible release of hazardous and/or radioactive wastes.	DSS-2 removed as part of Ra/Sr Treatment Systems removal action; DSS-7 closed in place; parts of DSS 1 and 5 leach system removed. Non-time critical removal actions were conducted at DSSs 3 and 6 in 2002 (Section 6.3).	Data adequate for risk assessment.
DSS 3	652			
DSS 4	545			
DSS 6	1,240			
Dog Pens Areas—Western	116,279	Potential source based on potential for radioactive animal waste and use of chlordane.	Non-time-critical removal action conducted in 2001 (Section 6.4.3).	Data adequate for risk assessment.

Table 6-1. Evaluation of LEHR Federal Facility Areas as Potential Contaminant Sources (continued)

LEHR Federal Facility Area ⁽¹⁾	Surface Area (sq ft)	Potential as Contaminant Source	Response Activities To Date	Investigation Data Adequacy
Dog Pens Areas – Eastern	35,030	Potential source limited to the upper two feet of soil based on potential for radioactive animal waste and use of chlordane.	None	Data adequate for risk assessment; additional data may be needed for remedy selection.
Southwest Trenches	16,663	Potential source based on known waste burial and chlordane application in area.	Non-time-critical removal action conducted in 1998 (Section 6.6.3).	Data adequate for risk assessment.
DOE Disposal Box	480	Potential source based on use for chemical/radionuclide disposal.	Time-critical removal action conducted in 1996 (Section 6.7.2)	Data sufficient for risk assessment.
Mixed Waste Storage Facility ⁽²⁾	N/A	Potential source based on construction and use for chemical/radioactive waste storage.	Closed and transferred to UC Davis (Section 2.4.2)	Data sufficient to indicate no measurable impact to environment.

Table 6-2. Pre-Removal Action Radium/Strontium Treatment Systems Investigations

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
1984	Initial Assessment Survey	Rockwell drilled six borings in the Ra/Sr Treatment Systems area down to depths of 20 feet. Approximately 23 soil samples were collected and analyzed for one or more of the following: Ra-226, Sr-90, plutonium-241, VOCs, SVOCs, pesticides, and metals. <i>Not performed under CERCLA.</i>	Rockwell, 1984
1987-1988	To determine if the soil was contaminated and, if so, determine the type and extent of soil contamination.	Wahler Associates drilled 13 borings in the vicinity of the Ra/Sr Treatment Systems area to depths of 25 feet. Thirteen individual and 13 composite soil samples were submitted and analyzed for gross alpha, gross beta, gross gamma, tritium and Sr-90. <i>Not performed under CERCLA.</i>	Wahler, 1989
March 1989	To characterize the liquid and sludge in the Ra/Sr tanks for disposal.	Samples collected by UC Davis were analyzed for SVOCs, radionuclides, VOCs, metals, and nitrate. <i>Not performed under CERCLA.</i>	D&M, 1994
March 1990	To determine if the soil was contaminated and, if so, determine the type and extent of soil contamination.	D&M drilled seven borings and collected 54 soil samples. The samples were analyzed for VOCs, SVOCs, pesticides/PCBs, metals and radionuclides. <i>Not performed under CERCLA.</i>	D&M, 1993
October 1990	To determine if the ground water was contaminated.	D&M drilled and installed one ground water monitoring well in the Ra/Sr Treatment Systems area (UCD1-22). Several soil samples were collected and analyzed for one or more of the following: VOCs, SVOCs, pesticides/PCBs, metals, hexavalent chromium, nitrate, and radionuclides. <i>Not performed under CERCLA.</i>	D&M, 1993

Table 6-2. Pre-Removal Action Radium/Strontium Treatment Systems Investigations (continued)

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
March 1992	To characterize the contents of the Imhoff tanks and determine if there was any soil contamination associated with the Ra tanks.	One sludge sample from Imhoff Tank A and four soil samples from beneath the Ra and Sr tanks were collected and analyzed for radionuclides. <i>Not performed under CERCLA.</i>	CWM, 1992
July through August 1996	To determine the vertical and lateral extent of soil contamination.	IT Corp. excavated five exploratory trenches and drilled five soil borings. A total of 75 soil samples from the trenches and soil borings were collected and analyzed for radionuclides, metals, VOCs, SVOCs, pesticides, and other inorganic compounds. <i>CERCLA investigation.</i>	WA, 1997f

Notes
⁽¹⁾ The lowest background concentration.
⁽²⁾ Chemical PRGs are from US EPA Region 9 PRGs Table, dated February, 2003. Radionuclide PRGs are from Radionuclide Toxicity and PRGs for Superfund, dated April14,2003 (US EPA, http://epa-prgs.orl.gov/radionuclides/download/rad_master_prg_table_pci.xls). The industrial PRGs for radionuclides are for "outdoor worker soil". California modified PRGs are shown in brackets.
⁽³⁾ The reasonable maximum is the 95% upper confidence limit on the true mean based on sample data.
⁽⁴⁾ Reanalysis indicated substantially lower result (Table 6-5).
⁽⁵⁾ Radium/Strontium Treatment Systems Areas specific RBAS value for mercury total chlordanes.
⁽⁶⁾ total chlordanes.
⁽⁷⁾ These concentrations represent the average of the uranium-233 and -234 PRGs.
⁽⁸⁾ Uranium-235+D

Notes

⁽¹⁾ Background activities (in picoCuries per gram) represent stratified concentration by depth: zero to four feet and less than four feet.

⁽²⁾ All units are picoCuries per gram.

Samples SSRSC034 and SSRSC035 were collected 42.5 feet below ground surface.

Notes

- ⁽¹⁾ Hexavalent chromium, mercury, nitrate, cadmium, and zinc in mg/kg or µg/l, all others in pCi/g or pCi/l.
- ⁽²⁾ Range of available data for nearby downgradient well UCD1-021.
- ⁽³⁾ Based on data from well UCD1-18.
- ⁽⁴⁾ MCL for total chromium.
- ⁽⁵⁾ Assumed to be mercuric sulfide.
- ⁽⁶⁾ First number is for 0 to 4 ft bgs, second is for > 4 ft bgs.
- ⁽⁷⁾ Assumed to be methanol.

Bold type indicates above background soil concentration above NUFT result for ground water impact at background levels, or ground water concentration above background.

Boxed type indicates above background soil concentration above NUFT result for ground water impact at MCL, or ground water concentration above MCL.

Table 6-7. Summary of Potential Impact of Designated-Level Constituents of Concern in Radium/Strontium Treatment Systems Area Soil on Ground Water (continued)

Abbreviations

BG	background
COC	constituent of concern
DL	designated-level
ft	feet
MCL	California Maximum Contaminant Level (primary) for ground water (November 2002)
mg/kg	milligrams per kilogram
N	nitrogen
NA	not applicable or not available
ND	not detected at a range of detection limits
NE	not established
NUFT	Non-Isothermal, Unsaturated Flow and Transport model
pCi/g	picoCuries per gram
pCi/l	picoCuries per liter
PRG	Preliminary Remediation Goal (US EPA, April 2003 for radionuclides; US EPA Region 9, February 2003 for other COCs)
UCL	upper confidence limit on the true mean based on sample data
US EPA	United States Environmental Protection Agency
µg/l	micrograms per liter

Table 6-8. Previous Domestic Septic Systems Investigations

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
1990	Locate the seven DSSs.	D&M located DSS 1, DSS 2 and DSS3. <i>Not performed under CERCLA.</i>	D&M, 1993
June 1995	Determine the extent of contamination in the vicinity of DSS 2.	PNNL collected soil samples around DSS 2. The samples were analyzed for radionuclides. <i>CERCLA investigation.</i>	PNNL, 1995a
August 1996	Determine the extent of contamination near DSS 1 and DSS 7.	IT Corp. excavated around DSS 1 and DSS 7. Soil samples were collected beneath each tank and analyzed for radionuclides, VOCs, SVOCs, metals, pesticides, and other inorganic compounds. <i>CERCLA investigation.</i>	WA, 1997f
June 1997	Determine the extent of contamination near DSS 1, and DSS 3 through DSS 6.	WA excavated two trenches near DSS 1 and drilled 37 borings in and around DSS 1, DSS 3, DSS 4, DSS 5, and DSS 6. Several soil samples were collected from the borings and analyzed for radionuclides, metals, VOCs, and other inorganic compounds. <i>CERCLA investigation.</i>	WA, 1997f
September 1997	Further evaluate the extent of contamination near DSS 1, DSS 3, DSS 4 and DSS 6.	WA collected twelve additional soil samples from DSS 1, DSS 3, DSS 4, and DSS 6. The samples were analyzed for radionuclides, metals, VOCs, and other inorganic compounds. <i>CERCLA investigation.</i>	WA, 1997f

Table 6-8. Previous Domestic Septic Systems Investigations (continued)

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
2001	Determine the location of the remaining DSSs and determine the extent of contamination in the vicinity of each DSS.	WA collected several soil samples from DSS 1, DSS 3, DSS 4, DSS 5, and DSS 6. The samples were analyzed for VOCs, SVOCs, PCBs, metals, Cr-VI, radionuclides and nitrate. Twenty-five samples were collected from five borings in the vicinity of DSS 1 and DSS 5 leach fields. The samples were analyzed for the same suite as the DSS samples. An additional nine samples from three additional borings were collected and analyzed for metals. <i>CERCLA investigation.</i>	WA, 2001g

Notes

⁽¹⁾ Chemical PRGs are from US EPA Region 9 PRGs Table, dated February, 2003. Radionuclide PRGs are from Radionuclide Toxicity and PRGs for Superfund, dated April 14, 2003 (US EPA, http://epa-prgs.ornl.gov/radionuclides/download/rad_master_prg_table_pci.xls). The industrial PRGs for radionuclides are for "outdoor worker soil." California-modified PRGs are shown in brackets.

Notes

- ⁽¹⁾ Uranium-235 in pCi/g or pCi/l; all other constituents in mg/kg or µg/l.
- ⁽²⁾ Based on data from well UCD1-18.
- ⁽³⁾ Nearest downgradient well is over 500 ft away.
- ⁽⁴⁾ Range of available data for nearby downgradient wells UCD1-020 and UCD1-024.
- ⁽⁵⁾ Background is specifically for > 4 ft below ground surface.
- ⁽⁶⁾ Assumed to be mercuric chloride.
- ⁽⁷⁾ Range of available data for nearby downgradient well UCD1-021.

Bold type indicates above background soil concentration above NUFT result for ground water impact at background levels, or ground water concentration above background.

Boxed type indicates above background soil concentration above NUFT result for ground water impact at MCL, or ground water concentration above MCL.

Abbreviations

- BG background
- COC constituent of concern
- DL designated-level
- ft feet
- MCL California Primary Maximum Contaminant Level for ground water (November 2002)
- mg/kg milligrams per kilogram
- N nitrogen
- NA not applicable or not available
- NUFT Non-Isothermal, Unsaturated Flow and Transport model
- pCi/g picoCuries per gram
- pCi/l picoCuries per liter
- PRG Preliminary Remediation Goal (USEPA, April 2003 for radionuclides; USEPA Region 9, February 2003 for others)
- US EPA United States Environmental Protection Agency
- µg/l micrograms per liter

Table 6-12. Domestic Septic System 3 Investigation Sampling Analytical Results Summary (continued)

Notes

Highlighted constituents (indicated with **bold type**) were detected above background and the lowest risk-based action standard.

¹ Site-specific background for greater than four feet below ground surface.

² The lowest risk-based action standard.

³ Chemical PRGs for residential soil are from US EPA Region 9 PRGs table, dated February, 2003. Radionuclide PRGs for residential soil are from Radionuclide Toxicity and PRGs for Superfund, dated April 14, 2003 (US EPA, http://epa-prgs.orrl.gov/radionuclides/download/rad_master_prg_table.xls).

⁴ Lead and chrysene were evaluated against California-modified PRGs.

Notes

⁽¹⁾ Background greater than 4 ft bgs.

⁽²⁾ Chemical PRGs for residential soil from US EPA Region 9 PRGs table, dated February, 2003. Radionuclide PRGs for residential soil from Radionuclide Toxicity and PRGs for Superfund, dated April 14, 2003 (US EPA, http://epa-prgs.orrl.gov/radionuclides/download/rad_master_prg_table.xls).

⁽³⁾ Chemical PRGs are from US EPA Region 9 PRGs Table, dated February, 2003. Radionuclide PRGs are from Radionuclide Toxicity and PRGs for Superfund, dated April 14, 2003 (US EPA, http://epa-prgs.orrl.gov/radionuclides/download/rad_master_prg_table_pci.xls). The industrial PRGs for radionuclides are for “outdoor worker soil”. California-modified PRGs are shown in brackets.

⁽⁴⁾ Mercury and compounds.

⁽⁵⁾ Total chlordane

⁽⁶⁾ Scenario 2 RBAS is specific to potential source soil in the Domestic Septic System 6 area.

Background Concentration = 80% lower confidence limit on 95th percentile of background data

> 4 ft bgs = Background statistic was determined from samples collected at depths greater than 4 feet below ground surface when constituent concentration was known to vary with depth.

Table 6-13. Confirmation Sampling Results Summary for Domestic Septic System 3 Removal Action (continued)

Abbreviations

95% UCL	95% upper confidence limit on the mean concentration
bgs	below ground surface
Carc.	based on carcinogenic toxicity
COCs	constituents of concern
ft	feet
mg/kg	milligrams per kilogram
N/A	not applicable
NC	not calculated
No.	number
Non-Carc.	Based on non-carcinogenic toxicity
PRG	Preliminary remediation goals for non-radionuclides (US EPA Region 9, 2000) and radionuclides (US EPA, 2001).
RAS	Background or lowest RBAS whichever is higher
RBAS	Risk Based Action Standard. 10^{-6} risk for carcinogenic effects and a hazard quotient of 1.0 for non-carcinogenic effects (WA, 1997).
RME	Reasonable maximum exposure concentration. The 95% UCL was used as the RME for all Domestic Septic System COCs.
$\mu\text{g}/\text{kg}$	micrograms per kilogram

Notes

⁽¹⁾ Chemical PRGs for residential soil are from US EPA Region 9 PRGs table, dated February, 2003. Radionuclide PRGs for residential soil are from Radionuclide Toxicity and PRGs for Superfund, dated April 14, 2003 (US EPA, http://epa-prgs.orrl.gov/radionuclides/download/rad_master_prg_table.xls). Constituents in brackets are California-modified PRGs.

⁽²⁾ The background concentration is for samples collected at depths greater than four ft bgs.

⁽³⁾ These concentrations represent the average of the uranium-233 and uranium-234 PRGs.

Abbreviations

bgs	below ground surface
ft	feet
ID	identification (number)
IDL	instrument detection limit
MDA	minimum detectable activity
MDL	minimum detection limit
mg/kg	milligrams per kilogram
N/A	not available
pCi/g	picoCuries per gram
PRG	preliminary remediation goal for residential soil (U.S. Environmental Protection Agency)
RBAS	lowest risk-based action standard

Table 6-21. Summary of Potential Impact of Designated-Level Constituents of Concern in Dry Wells A through E Area Soil on Ground Water

Constituent of Concern	Soil Sampling Results		Soil Background Value (mg/kg or pCi/g)	Equilibrium Soil Concentration		Downgradient Ground Water Concentration ⁽²⁾ (µg/l or pCi/l) ⁽¹⁾	Ground Water Background Concentration ⁽³⁾ (µg/l or pCi/l)	Ground Water MCL (µg/l or pCi/l)	Tap Water PRG (µg/l or pCi/l)
	Maximum (mg/kg or pCi/g) ⁽¹⁾	Depth of Maximum (ft)		BG Ground Water Goal (mg/kg or pCi/g)	MCL Ground Water Goal (mg/kg or pCi/g)

Notes

⁽¹⁾ Cesium-137 and strontium-90 in pCi/g or pCi/l; all others in mg/kg or µg/l.

⁽²⁾ No downgradient well located within 400 ft.

⁽³⁾ Based on data from well UCD1-18.

⁽⁴⁾ Background level is for > 4 ft below ground surface.

⁽⁵⁾ Assumed to be mercuric chloride.

Bold type indicates above background soil concentration above NUFT result for ground water impact at background levels, or ground water concentration above background.

Boxed type indicates above background soil concentration above NUFT result for ground water impact at MCL, or ground water concentration above MCL.

Abbreviations

- BG background
- DL designated-level
- ft feet
- MCL California primary maximum contaminant level for ground water (November 2002)
- mg/kg milligrams per kilogram
- NA not applicable or not available
- NE none established
- NUFT Non-Isothermal, Unsaturated Flow and Transport model
- UCL upper confidence limit on the true mean based on sample data
- US EPA United States Environmental Protection Agency
- µg/l micrograms per liter
- pCi/g picoCuries per gram
- pCi/l picoCuries per liter
- PRG preliminary remediation goal (US EPA, September 2002 for radionuclides; US EPA Region 9, October 2002 for others)

Table 6-22. Previous Western Dog Pens Investigations

Date	Investigation Objectives	Characterization Activity	Document Reference ¹
1984	Initial Assessment Survey	Rockwell conducted a surface soil survey within the WDPs. Approximately eight areas were surveyed. Based on the results of the surface soil survey, only one subsurface soil sample was collected and analyzed for Ra-226 and Sr-90. <i>Not performed under CERCLA.</i>	Rockwell, 1984
1987-1988	Determine if the soil was contaminated and, if so, determine the type and extent of soil contamination.	Wahler drilled 16, 10-ft borings within the WDPs. A total of 16 composite soil samples were analyzed for gross alpha, gross beta, gross gamma, tritium and Sr-90. <i>Not performed under CERCLA.</i>	Wahler, 1989
February through March 1990	Determine if the soil was contaminated and, if so, determine the type and extent of soil contamination.	D&M collected approximately 34 surface and near surface soil samples from 17 dog pens, and drilled 3 borings. The soil samples were analyzed for VOCs, SVOCs, radionuclides, metals, and inorganic compounds. <i>Not performed under CERCLA.</i>	D&M, 1993
October 1990	Determine if the ground water was contaminated and, if so, determine the type and extent of ground water contamination.	D&M installed four ground water monitoring wells: UCD1-20, -21, -23 and -24. <i>Not performed under CERCLA.</i>	D&M, 1993
December 1994	Determine the extent of soil contamination.	D&M drilled 19 borings in the WDPs and collected 44 soil samples. The soil samples were analyzed for SVOCs, VOCs, radionuclides, metals and pesticides. <i>CERCLA investigation.</i>	D&M, 1994

Table 6-22. Previous Western Dog Pens Investigations (continued)

Date	Investigation Objectives	Characterization Activity	Document Reference ¹
June through July 1996	Remove the dog pen pedestals and determine the degree of soil contamination in the vicinity of the pedestals.	During pedestal removal, 352 alpha and beta/gamma scans were conducted. Based on the scans, 24 soil samples were collected throughout the WDPs and EDPs. The samples were analyzed for radionuclides and two samples were analyzed for chlordane. <i>Not performed under CERCLA.</i>	WA, 1997f
October 1997	Collect additional data needed to make remedial decisions.	The DPI was conducted in three phases. Phases A and B consisted of a records review, surface radiation survey and collection of 46 gravel and 75 soil samples. The samples were analyzed for selected radionuclides, pesticides, mercury, hexavalent chromium, and nitrate. <i>CERCLA investigation.</i>	WA, 1998d
February through March 1998	Determine the extent of gravel and soil contamination.	Phase C of the DPI included drilling 20 borings and collecting 106 soil samples. The samples were analyzed for selected radionuclides, pesticides, mercury, nitrate, and hexavalent chromium. Approximately 32 samples from several borings were also analyzed for total chromium, ammonia, organic nitrogen, and total organic carbon. <i>CERCLA investigation.</i>	WA, 1998d

Notes

¹ Site-specific background levels, as presented in Appendix C from "Sampling and Analysis Plan for Removal Actions in the Southwest Trenches, Ra/Sr Treatment Systems, and Domestic Septic System Areas" (WA, 1999f).

² Using WRS Test with previously approved parameters; "Pass" indicates WDPs distribution statistically does not exceed the background distribution; "Q" indicates result is qualified due to insufficient data for WRS test based on Noether calculation.

³ Lowest RBAS from "Draft Final Determination of Risk-Based Action Standards for DOE Areas" (WA, 1997b).

⁴ "Pass" indicates maximum WDPs level is lower than lowest RBAS; "---" indicates comparison not made because constituent passes comparison with background.

⁵ "Pass" indicates RME level, defined as the 95% UCL on the mean, of WDPs data is lower than lowest RBAS; "---" indicates comparison not made because constituent passed previous comparison.

⁶ Chemical PRGs for residential soil are from US EPA Region 9 PRGs table, dated February, 2003. Radionuclide PRGs for residential soil are from Radionuclide Toxicity and PRGs for Superfund, dated April 14, 2003 (US EPA, http://epa-prgs.orrl.gov/radionuclides/download/rad_master_prg_table.xls). California-modified PRGs are shown in parentheses.

⁷ Where two background values are given, first is for surface to 4 ft bgs soil, second is for >4 ft bgs soil.

⁸ This new RBAS value is for mercuric sulfide and mercuric chloride. It is the result of RBAS recalculation presented in *Addendum to Former Dog Pens Technical Memoranda* (WA, 2000).

⁹ Indeterminate for samples greater than 4 ft bgs.

Notes

- ⁽¹⁾ Number of samples above reporting limit represents the number of samples greater than the “detection units” for volatile and semi-volatile organic compounds, pesticides, the instrument detection limit for metals, the minimum detection limit for general chemistry, and the minimum detectable activity for radionuclides.
- ⁽²⁾ Minimum value above laboratory reporting limit.
- ⁽³⁾ The average of all detected concentrations including those below the reporting limit. If the sample results were censored or negative, half the detection limit was used to calculate the average.

Notes

- ¹ The reasonable maximum is the 95% upper confidence limit on the true mean based on sample data.
- ² The background value is determined as the 80% lower confidence limit on 95th percentile of the background sample.
- ³ Western Dog Pens-specific risk-based action standard for mercuric sulfide.
- ⁴ There are fewer detections of total chlordane than of alpha and gamma chlordane due to generally higher detection limits reported by the analytical laboratory for total chlordane.

- NUFT Non-Isothermal, Unsaturated Flow and Transport model
- pCi/g picoCuries per gram
- pCi/l picoCuries per liter
- PRG preliminary remediation goal (US EPA April 2003 for radionuclides; US EPA Region 9, February 2003 for others)
- UCL Upper confidence limit on the true mean based on sample data
- US EPA United States Environmental Protection Agency
- µg/l micrograms per liter

Table 6-27. Previous Eastern Dog Pens Investigations

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
1984	Initial Assessment Survey	Rockwell conducted a surface soil survey within the EDPs. Approximately three areas were surveyed and based on the results of the surface soil survey, no subsurface samples were collected. <i>Not performed under CERCLA.</i>	Rockwell, 1984
1987-1988	Determine if the soil was contaminated and, if so, determine the type and extent of soil contamination.	Wahler drilled two borings within the EDPs to 10 ft bgs. A total of 16 composite soil samples were analyzed for gross alpha, gross beta, gross gamma, tritium and Sr-90. <i>Not performed under CERCLA.</i>	Wahler, 1989
February through March 1990	Determine if soil was contaminated and, if so, determine the type and extent of contamination.	D&M collected approximately 16 surface and near-surface soil samples from 8 dog pens. The soil samples were analyzed for VOCs, SVOCs, radionuclides, metals and inorganic compounds. <i>Not performed under CERCLA.</i>	D&M, 1993
June through July 1996	Ensure worker safety by determining if pedestals or underlying soil were significantly radioactive.	IT Corp. performed 352 alpha and beta/gamma scans during pedestal removal. Based on the scans, 24 soil samples were collected throughout the WDPs and EDPs. The samples were analyzed for radionuclides and two samples were analyzed for chlordane. <i>Not performed under CERCLA.</i>	WA, 1997f

Table 6-27. Previous Eastern Dog Pens Investigations (continued)

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
March 1999	Determine if the curbs, gravel and soil were contaminated and if so determine the type and extent of soil contamination.	WA collected six curb samples, 16 gravel samples and 37 soil samples from within the EDPs. The curb and gravel samples were analyzed only for Ra-226 and Sr-90. The soil samples were analyzed for selected radionuclides, metals, pesticides and nitrogen compounds. Four surface samples and four subsurface samples were analyzed for bulk density and moisture content. An additional six surface soil samples were collected and analyzed for tritium only. <i>CERCLA investigation.</i>	WA, 1999c
1999	Mercury speciation investigation was conducted to determine the mercury cleanup level.	WA collected three soil samples from the EDPs. The samples were analyzed for mercury compounds or species by a lab that specializes in these analyses. <i>CERCLA investigation.</i>	WA, 1999c

Notes

- ⁽¹⁾ Site-specific background levels, as presented in Appendix C in "Sampling and Analysis Plan for Removal Actions in the Southwest Trenches, Radium/Strontium Treatment Systems, and Domestic Septic System Areas" (WA, 1999f).
- ⁽²⁾ Using WRS with previously approved parameters; "Pass" indicates EDPs distribution statistically does not exceed the background distribution; "Q" indicates result is qualified due to insufficient data for WRS test based on Noether calculation.
- ⁽³⁾ Higher of background and lowest RBAS from "Draft Final Determination of Risk-Based Action Standards for DOE Areas" (Weiss Associates, 1997b).
- ⁽⁴⁾ "Pass" indicates maximum EDPs level is lower than lowest RBAS; "---" indicates comparison not made because constituent passes comparison with background.
- ⁽⁵⁾ The RME is defined as the 95% upper confidence limit on the mean.
- ⁽⁶⁾ "Pass" indicates 95% UCL on the mean of EDPs data is lower than lowest RBAS; "---" indicates comparison not made because constituent passed previous comparison.
- ⁽⁷⁾ Chemical PRGs for residential soil from US EPA Region 9 PRGs table, dated February, 2003. Radionuclide PRGs for residential soil from Radionuclide Toxicity and PRGs for Superfund, dated April 14, 2003 (US EPA, http://epa-prgs.orrl.gov/radionuclides/download/rad_master_prg_table.xls).
- ⁽⁸⁾ "BG" indicates the lowest calculated RBAS is less than background. Therefore, the lowest RBAS is defined as background.
- ⁽⁹⁾ RBAS and PRG for U-238 + Th-234.
- ⁽¹⁰⁾ Any values below reporting limits are estimated values (most of the concentrations for pesticides are below reporting limits).
- ⁽¹¹⁾ Indeterminate because no RBASs have been calculated. However, each constituent was detected only once and was below the PRG, when available.

Notes

- ⁽¹⁾ Number of samples above reporting limit represents the number of samples greater than the “detection units” for volatile and semi-volatile organic compounds, pesticides, the instrument detection limit for metals, the minimum detection limit for general chemistry, and the minimum detectable activity for radionuclides.
- ⁽²⁾ Minimum value above laboratory reporting limit.
- ⁽³⁾ The average of all detected concentrations including concentrations below the reporting limit. If the sample results were censored, half the detection limit was used to calculate the average.
- ⁽⁴⁾ Average of two analytical results for the same sample.

Notes

⁽¹⁾ Strontium-90 in pCi/g or pCi/l, all others in mg/kg or µg/l.

⁽²⁾ Range of data from downgradient well UCD1-13.

⁽³⁾ Based on concentrations in ground water from upgradient well UCD1-18.

⁽⁴⁾ MCL for total chromium.

⁽⁵⁾ Assumed to be mercuric sulfide.

⁽⁶⁾ Background is specifically for soil from 0 to 4 ft below ground surface.

Bold type indicates above background soil concentration above NUFT result for ground water impact at background levels, or ground water concentration above background.

Boxed type indicates above background soil concentration above NUFT result for ground water impact at MCL, or ground water concentration above MCL.

BG background

DDD dichlordiphenyl dichloroethane

Table 6-30. Potential Impact of Designated-Level Constituents of Concern in Eastern Dog Pens Area Soil on Ground Water (continued)

DDE	dichlordiphenyl dichloroethylene
DDT	dichlordiphenyl trichloroethane
ft	feet
MCL	maximum contaminant level for ground water (primary)
mg/kg	milligrams per kilogram
NA	not applicable or not available
NC	not calculated
NUFT	Non-Isothermal, Unsaturated Flow and Transport model
PCB	polychlorinated biphenyl
pCi/g	picoCuries per gram
pCi/l	picoCuries per liter
PRG	preliminary remediation goal (US EPA April 2003 for radionuclides; US EPA Region 9, February 2003 for others)
UCL	Upper confidence limit on the true mean based on sample data
US EPA	United States Environmental Protection Agency
µg/l	micrograms per liter

Table 6-31. Previous Southwest Trenches Area Investigations

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
1984	Initial Assessment Survey	Rockwell drilled four borings in the SWT area. Two samples were analyzed for one or more of the following: C-14, tritium, Ra-226 and Sr-90. <i>Not performed under CERCLA.</i>	Rockwell, 1994
1988	Determine if the soil was contaminated and, if so, determine the type and extent of soil contamination.	Wahler Associates excavated ten exploratory trenches to determine burial trench locations. Ten composite soil samples were analyzed for gross alpha, gross beta, tritium and Sr-90. <i>Not performed under CERCLA.</i>	Wahler, 1989
1989	Waste Burial Trench Investigation	D&M excavated 10 exploratory trenches to determine burial trench locations. Within each trench, composite samples were collected and analyzed for gross alpha, gross beta, tritium and Sr-90. <i>Not performed under CERCLA.</i>	Wahler, 1989
March 1990	Determine the extent of the soil and ground water contamination.	D&M drilled three borings and collected soil samples for VOC, SVOC, radionuclide, metal, and inorganic compound analysis. Monitoring well UCD2-15 was also installed and sampled for metals, hexavalent chromium, nitrate, pesticides, VOCs, SVOCs, radionuclides, total dissolved solids, formaldehyde, and cations, calcium, magnesium, potassium, sulfate, sodium, phosphate, chloride, and alkalinity. <i>Not performed under CERCLA.</i>	D&M, 1993
October 1990	Determine the extent of ground water contamination and the characteristics of the aquifer.	D&M installed monitoring well UCD1-23 and performed a slug test on the well. <i>Not performed under CERCLA.</i>	D&M, 1993
May 1992	Determine the location of the burial trenches and the extent of contamination.	D&M collected samples from ten trenches in the vicinity of the trenches Wahler excavated in 1989. <i>Not performed under CERCLA.</i>	D&M, 1993

Table 6-31. Previous Southwest Trenches Area Investigations (continued)

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
November 1994	Further delineate the locations of the burial trenches.	D&M conducted a ground-penetrating radar survey to help locate the buried trenches. <i>CERCLA investigation.</i>	Norcal, 1994
January 1995	Determine the extent of soil contamination.	PNNL collected and analyzed seven soil gas samples for VOCs. <i>CERCLA investigation.</i>	PNNL, 1995
May through June 1995	Evaluate geophysical/soil gas anomalies.	PNNL drilled two borings to evaluate geophysical/soil gas anomalies and collected three soil samples. <i>CERCLA investigation.</i>	PNNL, 1995
July through August 1996	Further delineate the location of the burial trenches and determine the extent of contamination.	IT Corp. conducted a surface radiation survey, excavated six exploratory trenches, and drilled three soil borings. A total of 38 soil and solid waste samples were collected from the trenches. All soil and solid waste samples were analyzed for select radionuclides, VOCs, SVOCs, pesticides, PCBs, metals, nitrates, anions, and pH. Four soil samples were analyzed for physical parameters. <i>CERCLA investigation.</i>	WA, 1997f

Table 6-33. Cobble/Gravel Area Analytical Results from the Southwest Trenches Removal Action (continued)

Notes

- ⁽¹⁾ Grid locations are estimated from field measurements.
- ⁽²⁾ Chlordane, mercury, hexavalent chromium, nitrate, radium-226 and strontium-90 analyses by EPA Methods 8080, 7471, 7196, 300.0, 901.1 and 905.0, respectively.
- ⁽³⁾ Defined in the Final Removal Action Work Plan (WA, 2001d).
- ⁽⁴⁾ Screening criterion is RBAS recalculated in 2001 using site-specific lithology and mercury species data (see Section 6.2.2.2).

Boldface identifies data points exceeding the screening criterion.

Abbreviations

bgs	below ground surface
Dup.	duplicate
EPA	United States Environmental Protection Agency
ft	feet
mg/kg	milligrams per kilogram
pCi/g	picoCuries per gram
Ra-226	radium-226
RBAS	risk-based action standard
Sr-90	strontium-90
µg/kg	micrograms per kilogram

Notes

⁽¹⁾ Chemical PRGs are from US EPA Region 9 PRGs Table, dated February, 2003. Radionuclide PRGs are from Radionuclide Toxicity and PRGs for Superfund, dated April 14,2003 (US EPA, http://epa-prgs.ornl.gov/radionuclides/download/rad_master_prg_table_pci.xls). The industrial PRGs for radionuclides are for "outdoor worker soil". California modified PRGs are shown in brackets.

⁽²⁾ The reasonable maximum exposure is the 95% upper confidence limit on the true mean based on sample data.

⁽³⁾ Screening criterion is RBAS recalculated in 2001 using site-specific lithology and mercury species data (see Section 6.2.2.2).

⁽⁴⁾ Total chlordane.

Table 6-38. Previous DOE Box Investigations

Date	Investigation Objectives	Characterization Activity	Document Reference ⁽¹⁾
1994	Determine the location of the DOE Box.	NORCAL conducted a geophysical survey in the vicinity of the DOE Box. Five soil gas probes were installed and sampled in the general area. The samples were analyzed for VOCs. <i>Not conducted under CERCLA.</i>	NORCAL, 1994
September through October 1996	Determine the type and extent of contamination at the DOE Box area.	IT Corp. excavated four trenches encountering gravel and labware. A total of 13 discrete and composite samples were collected and analyzed for one or more of the following: radionuclides, VOCs, SVOCs, metals, pesticides, inorganics, herbicides, and other physical parameters. <i>CERCLA investigation.</i>	IT Corp., 1997b

7. SUMMARY AND CONCLUSIONS

The nature and extent of contamination in the DOE RI Areas in soil, and potential impact of residual COCs in soil on ground water, surface water and air based on the LEHR Federal Facility RI, are summarized below. Conclusions based on these RI findings, including potential data gaps, are also presented.

7.1 Nature and Extent of Soil Contamination

The following summarizes the nature and extent of post-RA residual COC concentrations soil contamination and conclusions regarding the potential impact of residual COCs in soil on underlying ground water based on DL modeling and current data for the LEHR Federal Facility:

- Ra/Sr Treatment Systems—The human health risk analysis using the site-specific RBAS indicates the cumulative cancer risk associated with the Ra/Sr Treatment Systems area soil has been reduced to a nominal range of 10^{-4} to 10^{-6} and the non-cancer HQ was reduced below 1.0 for all COCs with the possible exception of Hg. The concentration distribution of Ra-226 in soil was indistinguishable from background. All Sr-90 concentrations in soil were below the site-specific lowest RBAS and industrial PRGs. The third driver COC, nitrate, was detected above background in only 8 of 68 soil samples, although several of these concentrations were significantly above background.

Based on the DL evaluation and the ground water concentrations in a nearby downgradient well, Cr-VI and Ra-226 remaining in soil in the Ra/Sr Treatment Systems area may impact local ground water above background but below the MCL, and remaining C-14 and nitrate may impact local ground water above background and the MCL. Ground water results from the nearest downgradient well suggest that actual impact, if any, from these COCs in Ra/Sr Treatment System area soil is minimal.

- DSSs—Based on all soil data representative of current conditions, the majority of the COCs in the vicinity of DST 1, DSS 4, DST 5, DSS 7, and Dry Wells A through E are below their respective background and RBAS values. Following the RAs at DSS 3 and DSS 6, the cumulative excess cancer risk presented by remaining COCs in these areas is also below 10^{-6} . The calculated cumulative non-cancer HQs are 3.22 for DSS 3 and 2.5 for DSS 6, with Hg contributing almost all of the risk.. DSS 7 was reportedly never used, and RI data support this understanding. DSS 2 was removed as part of the Ra/Sr Treatment Systems RA.

Based on soil results, DL modeling, and DI WET analyses, some COCs remaining in the DSS areas may impact local ground water above background, but the only potential impact above MCLs in the next thousand years is by: formaldehyde and nitrate in the DSS 3 area; Cr-VI in the DSS 4 area; and, Cr-VI, chromium, Hg, and silver in the Dry Wells A through E area.

As shown on Table 6-21, all of the DL COCs in the Dry Wells A through E area are present at concentrations that could result in localized ground water impact above background. In addition, the maximum Cr-VI, total chromium, Hg, and silver concentrations could also result in ground water impact above MCLs. With the exception of Cr-VI, none of these COCs has significantly impacted ground water at the LEHR Site, and there are other known sources for Cr-VI in ground water. However, there are no wells immediately downgradient of the Dry Wells A through E area, making the extent of local impact to ground water from the Dry Wells impossible to fully assess.

- WDPs—Based on the post-RA confirmation sampling results, vadose zone modeling, and downgradient ground water concentrations, all significant contamination associated with the WDPs area has been removed. The human health risk analysis using the site-specific RBAS indicates the cumulative cancer risk has been reduced to a nominal range of 10^{-4} to 10^{-6} and the cumulative non-cancer HQ was reduced below 1.0. The concentration distribution of driver COC Ra-226 was indistinguishable from background. All Sr-90 concentrations were below the site-specific lowest RBAS and industrial PRGs. In addition, residual COCs in WDPs soil are not expected to have any significant impact on ground water in the next thousand years.
- EDPs—Based on all CERCLA investigation data, Sr-90, chromium, Cr-VI, seven pesticides, and two PCBs were detected above background levels in EDPs soil. Of these, only dieldrin exceeded its site-specific lowest RBAS in one or more samples. Dieldrin also exceeded its residential and industrial PRGs in one or more samples. Chromium exceeded its residential PRG in two samples, but was below the site-specific lowest RBAS and industrial PRG in all samples. Concentrations of all other above-background COCs in all samples were below both the site-specific lowest RBASs and residential PRGs. Based on statistical analysis of the data, all COCs in the EDP soil are statistically below their respective RASs.

Based on the soil concentrations in the upper two ft of the EDPs and vadose zone modeling, it appears that COCs in EDPs' soil have not, and should not in the next several thousand years, have any significant impact on ground water. Although a well immediately downgradient of the EDPs has elevated concentrations of three of the EDPs' DL COCs (Cr-VI, chlordane, and dieldrin), these may originate from the underlying UC Davis Landfill Disposal Unit 2 and the disposal trenches east of the EDPs.

- **SWT**—Human health risk analysis using the site-specific RBAS indicates the cumulative cancer risk has been reduced to a nominal range of 10^{-4} to 10^{-6} and the cumulative non-cancer HQ was reduced below 1.0. The concentration distribution of Ra-226 was indistinguishable from background. All Sr-90 concentrations were below the site-specific lowest RBAS and industrial PRGs. Of those analytes statistically above background, only Hg was detected above its lowest RBAS, and no above-background analytes were detected above PRGs.

Based on the DL evaluation and ground water data from downgradient wells, tritium and zinc remaining in SWT area soil may impact local ground water above background, and Cr-VI and nitrate remaining in SWT area soil may impact local ground water above MCLs in the next several thousand years. However, based on actual ground water data from the SWT area, there is no evidence of above-background impact to ground water by any of these COCs.

- **DOE Box**—Based on all soil data representative of current conditions, human health risk associated with the DOE Box area soil has been reduced to 10^{-5} or less. The cumulative non-cancer HQ was calculated to be 4.3, with Hg contributing 3.95.

Based on soil data, DL modeling, and DI WET analyses, COCs remaining in the DOE Box area are unlikely to impact ground water above background for at least the next 1,000 years.

7.2 Potential Impact to Surface Water and Air

Eight metals and three pesticides have been detected above the lowest US EPA or California fresh water aquatic life criteria in one or more storm water samples collected from LS-1 at the LEHR Federal Facility. Of these constituents, only the pesticides and Hg are potentially related to DOE activities at the LEHR Site. Because no flow data are available for LS-1 or the Putah Creek discharge point, the impact, if any, of these low levels of Hg and pesticides on Putah Creek are unknown.

All air data collected to date indicate that LEHR Federal Facility and related RA activities have had no significant impact on air.

7.3 Plans for Additional Remedial Investigation Work

- Based on the RI results summarized above and the *Site-Wide Risk Assessment Work Plan* (UC Davis, 2002), DOE believes sufficient, valid data are available for all DOE areas to complete the SWRA. However, there is one data gap for the LEHR Federal Facility which needs to be resolved prior to the completion of the Feasibility Study: there are no ground water monitoring data downgradient

of Dry Wells A through E. In coordination with UC Davis, DOE will consider different options on how to address this issue. The RPMs will be notified prior to the collection of any data, and results will be presented at an RPM meeting and documented in the DOE Areas Feasibility Study.

APPENDIX A

DATA QUALITY EVALUATION

A. DATA QUALITY EVALUATION

Data management and validation procedures for Laboratory for Energy-Related Health Research (LEHR) soil, air, storm water, and ground water analyses are presented in this section. Only samples collected according to the November 1994 quality assurance/quality control (QA/QC) program requirements (D&M, 1994) in response to the LEHR Site National Priorities List (NPL) listing in April 1994 form the quantitative basis for conclusions presented in this report. LEHR Site samples that were not subject to the 1994 QA/QC program requirements are only considered qualitatively. Soil, air and storm water samples were collected, analyzed and reported according to the Quality Assurance Project Plan (WA, 2000) and Standard Operating Procedures (SOPs) (WA, 2001) and earlier versions for the DOE areas of the LEHR Site. Ground water data used in this report are from LEHR Site Annual Water Monitoring Reports submitted by the University of California, Davis (UC Davis). Specific ground water data QA/QC procedures are described and referenced in the Annual Water Monitoring Reports (URS, 2001). LEHR ground water samples were collected by DOE through 1996. Between 1996 and 2002, UC Davis collected LEHR ground water samples.

A.1 Data Management

Data management for the LEHR Federal Facility (i.e., DOE areas of the LEHR Site) consists of sample collection procedures, sample tracking, electronic data import QA, and field data import. Sample collection procedures including chain-of-custody, sample numbering, handling and shipment, etc. follow SOPs 1.1, 17.2, and 2.1 (WA, 2001), respectively. The sample tracking, electronic data import QA, and field data import procedures are described below.

Only detected data were used to determine the mean and standard deviation in 95% upper confidence limit (UCL) calculations. For the Wilcoxon Rank Sum test calculations, half of the lowest detected concentration for non-detect data was used.

When field duplicate samples were used in a statistical test, the highest concentration of the pair was selected and the lower concentration discarded. When samples were reanalyzed, the higher quality result was used and the lower quality result discarded. When original and reanalysis results were of the same data quality, the average of the results was used.

A.1.1 Sample Tracking

The LEHR Project Chemist manages all chemical and radiological analysis data for samples that are submitted to the off-site laboratory. A sample tracking spreadsheet is used to track each

sample from collection to final data package archiving. Tracking begins when a copy of the chain-of-custody record is given to the Project Chemist. The Project Chemist records the sample identification, laboratory receipt date, analysis requests, a brief description of the purpose of collecting each sample, and the data deliverable due date in a tracking spreadsheet.

The hard copy issuance date is recorded upon receiving the laboratory report. The Project Chemist or qualified designee validates the hard copy data. The data validation date is recorded in the sample tracking spreadsheet.

Upon completion of data validation, the electronic copy is imported into the project database. The laboratory hard copy, data validation report, and data import QA forms are then archived. The electronic copy import date and archive box number are recorded in the sample tracking spreadsheet for each laboratory deliverable.

A.1.2 Electronic Data Import Quality Assurance

Data import QA is tracked separately for each data deliverable and each analyte class. The LEHR analyte classes are volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides, polychlorinated biphenyls, metals, general chemistry parameters, and radiological analyses. Electronic data import procedures consist of four tasks:

1. Laboratory deliverable QA—The electronic copy of each deliverable is imported into a temporary database table and the Project Chemist or qualified designee compares the electronic copy to the hard copy report forms to verify agreement. If the electronic and hard copy data do not agree, the Project Chemist refers to the raw data package to resolve the differences. Corrections to the electronic copy are made while the data are stored in the temporary database table. The Project Chemist corrects minor errors in the hard copy. If the Project Chemist finds that hard copy corrections are extensive, the original hard copy is rejected and the laboratory issues a corrected copy.
2. Validation Qualifier Entry and QA—The Database Manager enters all data qualifications from the data validation process (Section A.2) into the data qualifier fields in the temporary database table. The Project Chemist or qualified designee verifies that the qualifiers in the temporary database table match the validation qualifiers.
3. QA Approval—The Project Chemist verifies that the laboratory deliverable QA and validation qualifier entry and QA are complete and approves the data for final electronic import.
4. Final Import—The Database Manager transfers the data from the temporary database table into the permanent database table.

A.1.3 Field Data Import

The position and depth of each sample are recorded in a field notebook at the time of sample collection. Field data are transferred from the field notebook into the sample database table following sample collection.

A.1.4 Location Data

The coordinates of removal action (RA) confirmation samples were surveyed by professional land surveyors licensed in the state of California. Survey data were received from the surveyors in electronic and hard copy form. The electronic data were imported into the sample database table.

A.2 Data Validation and Review Pursuant to Data Quality Objectives

Data review or full data validation was performed on 100% of the samples using the guidance of the United States Environmental Protection Agency (US EPA) Contract Laboratory Program National Functional Guidelines for Organic Data Review (US EPA, 1998a) and US EPA Contract Laboratory Program National Functional Guidelines for Inorganic Data Review (US EPA, 1998b). Full data validation was performed on 10% of site investigation and confirmation samples, and data review was performed on the remaining 90%. The SOP and checklists for organic, metals, general chemistry, and radiochemistry data validation are provided in Attachment 1 of SOP 21.1 (WA, 2001).

Organic data are reviewed for holding times, blank analysis results, gas chromatograph/mass spectrometer tuning, instrument calibrations, internal standard areas, laboratory control samples, matrix spike/matrix spike duplicate, and surrogate recovery. Metals, general chemistry and radiochemistry data are reviewed for holding times, blank analysis results, matrix spike/matrix spike duplicate /sample duplicates, laboratory control samples, and instrument calibrations. Analytical results are qualified as a result of the data validation process in accordance with the qualifying conventions listed in Attachment 6.2 of SOP 21.1 (WA, 2001). The qualifying conventions are shown in Tables A-1 and A-2.

A.3 Data Assessment

The data used in this report are post-October 1994 contract laboratory results intended to characterize the current condition of the DOE areas at the LEHR Site. The laboratory results apply to:

- All soil or solid samples used for site characterization or RA confirmation in DOE areas that were collected after the Site was listed on the NPL.

- Ground water samples from wells UCD1-13, UCD1-20, UCD1-21, UCD1-23, and UCD1-24 (UC Davis wells used to assess potential ground water impact from DOE areas) and all storm water monitoring samples collected through 2001.
- All air monitoring samples.

The data assessment identifies and discusses all data that were rejected due to analysis failure, explains the rationale for excluding or averaging specific types of data, and identifies all data that contain analytical bias that may significantly impact data use.

A.3.1 *Rejected Data*

If samples were re-collected in the field or re-analyzed at the laboratory due to rejection of the data, the rejected hard copy and electronic copy were discarded and only the data from re-collection or re-analysis was retained. No rejected data were used in assessing the nature and extent of contamination in DOE areas.

Sample results are rejected with an "R" qualifier when an expert reviews the laboratory data and finds evidence of serious deficiencies in the ability to analyze a sample and meet QC criteria. The "R" qualifier indicates that the data cannot be used to verify whether the analyte was present or absent from the sample. If an "R" qualified concentration or quantitative value is reported for the analyte, it should not be assumed to be present in the sample. Likewise, if an "R" qualified, not-detected result is reported for the analyte, the sample cannot be assumed clean. It should not be assumed that the analyte is not present.

Deficiencies indicated by an "R" qualifier may result from human error, analytical instrumentation failure in the laboratory or the sample may contain chemicals or physical properties that interfere with the method of analysis. The deficiencies are identified when QC criteria are not met. QC criteria that have indicated serious deficiencies in some LEHR data are calibration failure, significantly exceeded holding times, laboratory control sample recovery failure, matrix spike recovery failure, and surrogate spike recovery failure. Each of these deficiencies and the associated samples are discussed below.

A.3.1.1 Calibration Failure

A.3.1.1.1 Soil

Calibration failure contributed to the decision to reject 34 of 105,393(0.03%) LEHR soil sample results (Table A-3) because the analyte was not detected and calibration failure occurred. Because of these circumstances it was not possible to conclude that the analyte was not present even though the result was not-detected. Rejected results were for 1,2-dibromo-3-chloropropane, 3-nitroaniline, 4-chloroaniline, 2-butanone, and acetone, which are not constituents of concern (COCs) for the LEHR Federal Facility.

A.3.1.1.2 *Water*

Calibration failure contributed to the decision to reject 61 of 56,275 (0.1%) water sample results (Table A-4) because calibration failure occurred and the analyte was not detected in the sample. Rejected results were for acetone, methylene chloride, and other VOCs which are not considered COCs for the LEHR Federal Facility. Acetone and methylene chloride are common laboratory contaminants and are likely false-positive results.

A.3.1.1.3 *Air*

No air data were rejected due to calibration failure.

A.3.1.2 **Significantly Exceeded Holding Time**

A.3.1.2.1 *Soil*

Significantly exceeded holding times contributed to the decision to reject 42 of 105,393 (0.04%) LEHR soil sample results (Table A-3) because the analyte was not detected in the sample and the holding time was significantly exceeded. Therefore it was not possible to conclude that the analyte was not present on the day the sample was collected even though the result was not detected. Rejected results were for chloride, nitrate (10 results) and sulfate. With the exception of nitrate, the rejected data were not for analytes considered COCs for the LEHR Federal Facility.

A.3.1.2.2 *Water*

No water data were rejected due to exceeding holding times.

A.3.1.2.3 *Air*

No air data were rejected due to exceeded holding times.

A.3.1.3 **Laboratory Control Sample Recovery Failure**

A.3.1.3.1 *Soil*

Laboratory control sample recovery failures contributed to the decision to reject 59 of 105,393 (0.06%) LEHR soil sample results (Table A-3) because the analyte was not detected in the sample and the analyte recovery in the laboratory control samples was significantly below the QC limit. Therefore, it was not possible to conclude that the analyte was not present even though it was not detected during analysis. Rejected results were for 1,2,4-trichlorobenzene, 1,4-dichlorobenzene, and N-nitrosodipropylamine. None of the rejected data are considered COCs for the LEHR Federal Facility.

A.3.1.3.2 *Water*

No water data were rejected due to laboratory control sample recovery failure.

A.3.1.3.3 *Air*

Laboratory control sample recovery failures contributed to the decision to reject six LEHR air sample results (Table A-5) because they were not detected and the laboratory control sample recoveries were below the control limits for those analytes. Rejected results were for silver, which is not considered a LEHR Federal Facility COC.

A.3.1.4 **Matrix Spike Recovery Failure**

A.3.1.4.1 *Soil*

Matrix spike recovery failures contributed to the decision to reject 90 of 105,393 (0.09%) LEHR soil sample results (Table A-3). These results were rejected when the analyte was not detected in the sample and the analyte recovery in the matrix spike was significantly below the QC limit. Consequently, it was not possible to conclude that the analyte was not present in the sample even though the result was not detected. Rejected results were for formaldehyde, sulfide, and antimony. Formaldehyde and antimony are COCs for the LEHR Federal Facility. Antimony matrix spike failure is common for most soil types and is known by the US EPA to fail frequently. Formaldehyde matrix spike recovery occurred for only four samples used in Western Dog Pens site characterization.

A.3.1.4.2 *Water*

No water data were rejected due to matrix spike recovery failure.

A.3.1.4.3 *Air*

No air data were rejected due to matrix spike recovery failure.

A.3.1.5 **Surrogate Spike Recovery Failure**

A.3.1.5.1 *Soil*

Surrogate spike recovery failures contributed to the decision to reject 61 of 105,393 (0.06%) LEHR soil sample results (Table A-3) because the analyte was not detected in the sample and the surrogate recovery was significantly below the QC limit. It was not possible to conclude that the analyte was not present in these samples even though the result was not detected. Rejected results were for SVOCs in sample LEHR-S-359.

A.3.1.5.2 *Water*

No water data were rejected due to surrogate spike recovery failure.

A.3.1.5.3 *Air*

No air data were rejected due to surrogate spike recovery failure.

A.3.2 *Other Qualified Data*

A percentage of data used in this report were qualified with J, U, or UJ qualifiers. The data and qualifiers are shown in the Table of Analytic Results presented in the electronic deliverable that is provided in Appendix E. No data qualifications were necessary for 83% of detected soil sample results, 89% of detected water sample results, and 91% of detected air sample results.

Application of the J qualifier to analytical data means that the analyte was positively identified in the sample, but the analytical result is an approximation of the analyte concentration in the sample. The J qualifier was applied to 5% of soil data, 2% of water data, and 5% of air data.

Application of the U qualifier means the laboratory analyzed for the analyte, but the analyte was not detected above the reported sample detection limit (non-detect results). The U qualifier (non-detect) was applied to 69% of soil data, 77% of water data, and 60% of air data used in this report.

Application of the UJ qualifier means the analyte was not detected above the reported quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample. The UJ qualifier was applied to 8% of soil data, 6% of water data, and 11% of air data used in this report. The quantitation limit is greater than the detection limit and it represents the lowest level that the concentration value is accurate and precise.

A.3.3 *Excluded and Averaged Data*

Some site characterization and RA confirmation data were excluded (not used) or averaged. The reasons for excluding or averaging data were:

- Sample extract dilution—Neat extract organic data were excluded for an analyte when the concentration was above the calibration range in the neat extract and within the calibration range in the diluted extract. Diluted extract data were excluded when analytes were below the calibration range of the dilute analysis.
- Sample re-analysis—Results for samples that were analyzed twice, for reasons other than extract dilution, were either excluded or averaged. An analytical result was excluded if it had lower data quality than the other results for the same sample. Original and re-analysis results were averaged if the data were all of the same quality based on the data validation results.
- Field duplicates—The lower concentration result was excluded for each field duplicate pair. If both samples had the same concentration or were not detected at the same detection limit. One result was arbitrarily excluded. If the analyte was not-detected in both samples and the detection limits were different, the result with the higher detection limit was excluded.

Excluded or averaged data are qualified with E or A, respectively, in the Exc_Avg field of the LEHR database.

A.3.4 Data with Known Bias

Laboratory and/or validation review found blank contamination bias in some of the RA confirmation data used in this report. Data with known bias were flagged with a qualifier and reason code to indicate the source of the bias.

The most notable occurrence of bias in RA confirmation data was blank contamination in hexavalent chromium (Cr-VI) results. The Cr-VI data that were qualified for blank contamination are shown in Table A-6. Blank contamination is an indication that a significant quantity of the analyte is present in the laboratory reagents and/or laboratory equipment. Presence of the analyte in laboratory reagents or equipment can bias the sample data in one of two ways:

- The laboratory may detect the analyte when it is not actually present in the sample; or,
- The laboratory result may be significantly greater than the true concentration in the sample.

Blank contamination is a concern if it is significant in comparison to the remedial action or ground water resource protection standards. Soil risk-based action standard (RBAS) and background values are standards used to make field decisions regarding excavation extent and for DL analysis. Blank contamination is a concern for Cr-VI data because the LEHR soil background concentration (0.054 milligrams per kilogram [mg/kg]) was sometimes exceeded by laboratory contamination found in the blank quality control sample. Cr-VI data that have blank contamination qualifiers should not be compared to background because a background comparison will result in a decision error.

The DOE areas with hexavalent chromium data that have a known positive bias due to blank contamination and the percentages of these qualified data are:

Southwest Trenches Area – 16%

Domestic Septic System 4 – 50%

Dry Wells Area – 20%

Radium/Strontium Treatment Systems Area – 9%

Western Dog Pens – 25%

The percentage of hexavalent chromium contaminated soil blanks for all DOE Areas data was 14% of soil blanks analyzed. The percentages of hexavalent chromium blank contamination are

significant enough to cause DOE areas to fail the sensitive statistical tests used to evaluate cleanup attainment and could result in a decision to initiate cleanup in areas that have attained background concentrations.

The positive bias in hexavalent chromium data for DOE Areas soil samples was also compounded by a negative bias in hexavalent chromium results for background soil samples collected in 1997. The two forms of bias are a compounded problem because background is a primary point of comparison for DOE Areas data. All of the hexavalent chromium results for background soil samples collected in 1997 were qualified due to matrix spike recoveries below control limits, which indicates the negative bias. The hexavalent chromium background value of 0.054 mg/kg carries this bias because it was determined using only 1997 background data.

The negative bias in hexavalent chromium soil background was likely due to the sample preparation method used by the laboratory. The background soil samples were prepared following California Air Resources Board (CARB) Method 425, which was designed for air samples rather than soil matrices. Subsequent samples were prepared following EPA Method 3060A, which was designed for soil matrices.

In addition, blank contamination was near or above background and/or RBAS values for some antimony, molybdenum, silver, and plutonium-241 (Pu-241) RA confirmation data (Table A-6). The background and/or RBAS values for these analytes are:

- Antimony (background = 1.4 mg/kg, lowest RBAS = 0.3 mg/kg);
- Molybdenum (background is below the 0.26 mg/kg detection limit);
- Silver (background = 0.55 mg/kg, lowest RBAS = 3.8 mg/kg); and,
- Pu-241 (background is below the 0.5 picoCuries per gram (pCi/g) detection limit, lowest RBAS = 3.2 pCi/g);

Blank contamination also occurred for nitrate, acetone, methylene chloride, toluene, xylenes, 4,4'-dichlordiphenyl dichlor, and 4,4'-dichlordiphenyl trichlor analysis; however, the bias did not significantly impact these data because the blank concentrations were well below RBAS or background values.

One plutonium-241 result was identified as a significant outlier and discarded during the ground water impact evaluation in Section 6.2.5. The plutonium-241 outlier was 33.2 pCi/g in soil sample SSRSC034. Sample SSRSC034 was twice re-analyzed by the laboratory to verify the initial plutonium-241 concentration. The re-analysis results were 0.792 pCi/g and 0.476 pCi/g. Because the initial plutonium-241 result was not confirmed, the outlier was eliminated from the water quality screening evaluation.

Table A-1. Data Validation Qualifier Definitions

The following definitions provide brief explanations of the data validation qualifiers assigned to results in the data review process.

Flag	Data Qualifier Definition
U	The analyte was analyzed for, but was not detected above the reported sample quantitation limit.
J	The analyte was positively identified; the associated numerical value is the approximate concentration of the analyte in the sample.
N	The analysis indicates the presence of an analyte for which there is presumptive evidence to make a “tentative identification”.
NJ	The analysis indicates the presence of an analyte that has been “tentatively identified” and the associated numerical value represents its approximate concentration.
UJ	The analyte was not detected above the reported sample quantitation limit. However, the reported quantitation limit is approximate and may or may not represent the actual limit of quantitation necessary to accurately and precisely measure the analyte in the sample.
R	The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.

Table A-2. Data Validation Reason Code Descriptions

The following descriptions provide brief explanation of the cause for qualification of the results determined in the data review process. These reason codes are used in combination with the data qualifier, i.e. "Uz" indicates the analyte is non-detect due to method blank contamination.

Flag	Reason Code Description
c	Calibration failure; poor or unstable response.
d	Matrix duplicate imprecision or matrix spike/matrix spike duplicate imprecision.
f	Field replicate or duplicate imprecision.
h	Holding time violation.
i	Internal standard failure.
k	Serial dilution imprecision.
l	Laboratory control sample (LCS) recovery failure.
m	Matrix spike/matrix spike duplicate (MS/MSD) recovery failure.
n	Interference check sample recovery failure.
q	Below CRQL/CRDL or above calibration range.
s	Surrogate spike recovery failure.
v	Detected concentrations > 25% difference between 2 GC columns (Pesticides).
z	Blank contamination.

Table A-3. Summary of Rejected Soil Sample Data (continued)

Notes

- R The sample results are rejected due to serious deficiencies in the ability to analyze the sample and meet quality control criteria. The presence or absence of the analyte cannot be verified.
- c Calibration failure; poor or unstable response.
- h Holding time violation.
- l Laboratory control sample recovery failure.
- m Matrix spike/matrix spike duplicate recovery failure.
- s Surrogate spike recovery failure.

Abbreviations

CATAN	cations and anions
Class	chemical characteristic classification
DP	dog pens area
DSS	domestic septic system
GEN	general chemistry parameters
ID	identification (number)
METAL	metals
PES	pesticides and polychlorinated biphenyl compounds
RA/Sr	radium strontium treatment systems
STA	southwest trenches area
SVOC	semivolatile organic compound
VOC	volatile organic compound
µg/kg	microgram per kilogram

APPENDIX B

2001 DOMESTIC SEPTIC SYSTEM INVESTIGATIONS

B. 2001 DOMESTIC SEPTIC SYSTEM INVESTIGATIONS

B.1 Introduction

Investigations of the Laboratory for Energy-Related Health Research (LEHR) Domestic Septic Systems (DSSs), prior to 2001, could not locate some of the tanks and leach fields, or did not completely characterize some of the known tanks, leach fields, or the dry wells discovered during the 1999 Radium/Strontium (Ra/Sr) Treatment Systems Removal Action (RA). The purpose of the 2001 Domestic Septic Systems Investigation (DSSI) was to further determine the presence, if any, of constituents of concern (COCs) at DSSs 1, 3, 4, 5, 6 and 7 (Figure B-1) with sufficient certainty to obtain No Further Action (NFA) closure, or alternatively to recommend appropriate RAs or another appropriate remedy necessary to obtain NFA closure. DSS 2 was not included in the 2001 DSSI because it was removed during the Ra/Sr Treatment Systems RA. The 2001 DSSI is summarized below. Results and conclusions based on the DSSI are discussed in Section 6.3 of the LEHR Remedial Investigation (RI) text.

B.2 Sampling Approach

The COCs for the DSSI included a wide range of constituents, because many activities occurred at the Site, and the laboratory sinks that drained to the DSSs may have been used to dispose small quantities of a variety of chemicals. Therefore, samples from each DSS were analyzed for the full suite of COCs historically found at LEHR, including volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides/polychlorinated biphenyls (PCBs), radionuclides, metals, hexavalent chromium (Cr-VI), and nitrate.

The following sampling approach for the 2001 DSSI was presented in the *Final Domestic Septic Systems Investigation and Removal Action Work Plan* (WA, 2001).

Phase I screening samples were collected as follows:

- One tank contents sample was collected from the interior bottom of each domestic septic tank (DST) (sludge/sediment layer just above concrete tank floor). If an inadequate volume of tank contents was present, the surface of the concrete floor of the tank was also sampled.
- Two samples were collected on opposite sides of the exterior of each DST: one below the inlet and one below the outlet, located approximately one foot (ft) below the level of the bottom of the tank, within one ft horizontally of the tank wall.

- One sample was collected beneath the point of first perforation of each leach line, or a single composite sample was collected if more than one leach line was present downstream of the DST or distribution box (DB).
- Four samples were collected from boreholes drilled two ft horizontally from the axis of the dry well. Samples were collected at 10-ft depth intervals between 10 and 40 ft deep (inclusive).
- Fifteen samples were collected from five boreholes surrounding a radium-226 (Ra-226) detection of 1.5 picoCuries per gram (pCi/g) south of DSS 3. Samples were collected at four-ft depth intervals, starting at eight ft below ground surface (bgs).

The Phase I samples were screened in the field for Ra-226, mercury (Hg), chromium (Cr) and lead (Pb). The screening criteria (SC) are based on cleanup criteria and field analytical instrument detection limits and were: Hg (10 milligrams per kilogram [mg/kg]), Cr (700 mg/kg), Pb (10 mg/kg) and Ra-226 (0.75 pCi/g). If necessary, additional samples (Phase II) were collected immediately as follows:

- DST exterior—An additional sample was collected at a depth of five ft below the sample with COCs above the SC.
- Leach lines—For each discrete sample with a screening analysis above background and risk-based action standards (RBASs), and for each multi-point screening composite sample with results greater than the SC divided by the number of leach lines present, one discrete sample was collected five ft deeper than the previous sample and one discrete sample was collected from the estimated mid-point of the leach line.
- Dry wells—For each sample with COCs above background and RBASs, an additional borehole was drilled seven ft horizontally from the axis of the dry well. Samples were collected at the same depth and ten ft deeper than the samples with COCs if that depth was above the seasonal water table.

Regardless of whether there were COCs detected above the SC in the Phase I field analyses, a full suite of laboratory analyses were run for all COCs for each sample collected. All Phase II samples were discrete samples that were analyzed for VOCs, SVOCs, pesticides/PCBs, radionuclides, metals, Cr-VI, and nitrate. Any deviations from this sampling approach are discussed in Sections B.4 through B.10.

B.3 Site Setup

Prior to commencing field activities, a geophysical survey was conducted to attempt to locate buried structures at all the DSS areas. Ground penetrating radar, electromagnetic induction and ambient techniques were used to identify underground utilities and subsurface anomalies at all of the DSS investigation areas. Temporary fencing was installed around each investigation area perimeter

prior to starting the investigation. Temporary overburden stockpiles were established adjacent to the investigation areas.

B.4 Domestic Septic Tank 1

Field work began on August 13, 2001 at DSS 1. DSS 1 was the first system to be investigated because it was easily accessible, unobstructed by underground utilities and located during the 1996 Limited Field Investigation. DSS 1 is located west of the Institute of Toxicology and Environmental Health main office building (Figure B-1).

A section of asphalt measuring approximately ten ft by ten ft was sawcut and removed above DST 1. A backhoe was used for all of the asphalt and soil removal. The overburden soil was removed above DST 1 and stockpiled adjacent to the excavation on high-density polyethylene (HDPE) sheeting.

Concrete fragments were first encountered at 18 inches (in.) bgs. The southern sidewall of the circular tank was exposed using the backhoe. The tank's top was not present. DST 1 is constructed of four-inch thick concrete, and is five ft in diameter and six ft deep. Four-inch terra cotta influent and effluent lines were located at 1.8 ft bgs on the eastern and western sides of the DSS 1 excavation. Excavation continued along the western and southern edges of DST 1 to locate the tank bottom. The tank bottom was located at a depth of eight ft.

A Phase I soil sample, SSD1C001, was collected beneath the effluent line at 8.7 ft bgs on the western side of the tank using a hand auger (Figure B-2). The Phase I soil sample was shipped off site and analyzed for a full suite of COCs. A screening sample was analyzed on site for Ra-226, Pb, Cr and Hg. The screening sample's analytical results were below acceptable levels; therefore, Phase II sample collection was not necessary.

All of the tank's contents were removed to determine if a sludge/sediment layer was present on the tank bottom. There were no signs of sludge, sediment or any type of discoloration. It appeared that DST 1 may have been cleaned prior to being filled with sand. The southern tank wall was removed to sample the interior concrete floor of DST 1. A section of the tank floor was removed using the backhoe bucket, sampled and sent off site for a full suite of analyses. A land survey crew then surveyed the sample location, pipes, tank and excavation boundaries. The DSS 1 investigation area was backfilled and compacted to grade with the excavated material and base rock.

B.5 Domestic Septic System 3

The DSS 3 RA was conducted from April to July 2002. Reporting of the DSS 3 investigation and post-removal confirmation results is provided in the "*Draft Domestic Septic Systems 3 and 6 Removal Action Confirmation Report*" (Weiss Associates, 2002).

B.6 Domestic Septic System 4

Investigation activities at DSS 4 began on August 28, 2001. Prior to excavating DSS 4, the IT Corporation (IT Corp.) crew probed for utilities in the upper three ft of soil. All of the water, sewer, gas and electrical lines within the investigation area were located and marked for future reference. Excavation began approximately four ft south of Building H-217 and two ft northeast of the Specimen Storage Building (Figure B-3). The top of DST 4 was located approximately two ft bgs. It appeared that DST 4 was poured in place. The area east of DST 4 was excavated to determine the tank depth. The tank's dimensions are 5 ft long by 4.5 ft wide by 5 ft deep.

An aluminum casing was driven through an open hatch into the DST 4 tank's bottom. The tank fill contained in the casing was removed using a hand auger. The hand auger cuttings were emptied onto HDPE sheeting to examine the fill for discoloration, moisture and other indicators that sludge or sediment was present in the tank. No sludge was present in DST 4; therefore, a tank contents sample was not collected. A sample from the DST 4 tank floor could not be collected due to utility interference and limited access. A Phase I sample could not be collected on the inlet (eastern) side of DST 4 because this sample location was beneath a live electrical line and close to a concrete support wall (Figure B-3).

A Phase I sample, SSD4C001, was collected beneath the effluent line on the western side of DST 4 (Figure B-3) approximately 7.8 ft bgs. The sample was analyzed on site and shipped off site for a full suite of analyses. The screening sample results were below SC, therefore Phase II sample collection at this location was not necessary.

A terra cotta effluent line was encountered three ft bgs leading to a DB located five ft east of the tank (Figure B-3). The DB was constructed of four-inch thick concrete and had a wooden baffle running in a north-south direction that separated the box into two compartments. The DB dimensions 3.75 ft by 3.75 ft deep. A small volume of sediment was present in the DB. All of this sediment was removed for on-site analysis, which indicated that this sediment had an elevated concentration of lead (approximately 50 mg/kg compared to the 9 mg/kg background level).

Leach lines were present on the southern and western edges of the DB. The perforated Orangeberg (rolled "tar paper"-type material) leach lines are bedded in one-inch to two-inch rounded gravel. A two-point composite Phase I soil sample and a field duplicate were collected beneath the first points of perforation on the leach lines (Figure B-3). These samples were collected from the soil that was intermixed with the leach field gravel because this is the most likely location of contamination. The samples were analyzed on site and shipped off site for a full suite of analyses. The screening samples had elevated lead concentrations; therefore, Phase II sampling was conducted.

Phase II samples were collected at the "midpoint" of the southern leach line and five ft deeper than the Phase I samples at the first point of perforation on the western leach line. A Phase II sample was not collected five ft deeper at the first point of perforation on the southern leach line, because there was existing data from that location. A Phase II sample was not collected at the

midpoint of the western leach line because this location was under the Clinical Pathology Building. Both Phase II samples were shipped off site and analyzed for a full suite of analyses.

DSS 4 and the sample locations were then surveyed by a land survey crew. The DB was filled with clean sand and the DSS 4 investigation area was backfilled and compacted with the excavated material.

B.7 Domestic Septic Tank 5

Investigation activities at DST 5 began on August 21, 2000. The concrete sidewalk was saw cut, broken up with a hydraulic backhoe attachment and removed above the suspected location of DST 5 (Figure B-4). The concrete pieces were transported to the former Co-60 Field for temporary storage and later disposed as sanitary waste.

DST 5 was located approximately 1.5 ft bgs, with its northern half beneath the main office building of the Center for Health and the Environment (Figure B-4). The exterior dimension of DST 5 is 11 ft long by 5 ft wide by 6 ft deep. The tank's two compartments each have a 2.25 ft-diameter hatch. A clean aluminum casing was driven into the tank fill through the open eastern hatch. Water was observed at the bottom of DST 5. A water sample was collected from the casing and shipped off site for a full suite of analyses.

No influent line was present at DST 5. A concrete plug was present on the eastern edge of the tank. A Phase I sample was not collected on the inlet side of DST 5 because the area contained imported fill that sloughed from under the building, which made sample collection impossible. A Phase I sample was collected beneath the effluent line seven ft bgs on the western side of DST 5 (Figure B-4). The sample was screened on site and analyzed off site for a full suite of analyses. The screening sample results were below acceptable levels, therefore no Phase II samples were collected. The soil sample location was surveyed prior to backfilling and compacting the area.

B.8 Domestic Septic System 6

The DSS 6 RA was conducted from April to July 2002. Reporting of the DSS 6 investigation and post-removal confirmation results is provided in the "*Draft Domestic Septic Systems 3 and 6 Removal Action Confirmation Report*" (Weiss Associates, 2002).

B.9 Domestic Septic System 7

Investigation activities at DSS 7 were conducted on August 27, 2001. Excavation to locate DST 7 began approximately 15 ft north of the northern corner of the Co-60 Building. During prior DSS investigations, existing sewer lines were observed above abandoned septic tanks. Therefore,

exploratory trenching was conducted along a sewer line leading out of the Co-60 building. The maximum excavation length was 15 ft long and maximum width was 5.3 ft.

Large pieces of concrete were observed at the suspected location of DST 7. These possible tank fragments were intermixed with native soil and sand. Field staff determined that DST 7 had been demolished and that representative samples could not be collected. The area was backfilled and compacted to grade with the excavated material.

B.10 Dry Wells A, B, C, D and E

Drilling at Dry Wells A through E was conducted on September 26, 27 and 28, 2001. The areas surrounding the residual lower portions of Dry Wells A through E (the DSS 1 and 5 Leach Field) were sampled by direct-push drilling. Phase I soil samples were collected at 10-, 20-, 30-, and 40-ft intervals from a borehole located approximately 2 ft from the axis of each dry well and shipped off site for a full suite of analyses. Three additional borings were drilled surrounding Dry Well D to determine if the 1999 RA successfully removed the contamination associated with sample CWRSC024 (Figure B-5). All of the borings were drilled within two ft of the axis of the dry well. Samples were collected from these borings at 10, 15 and 20 ft bgs and analyzed off site for metals. All boring locations are shown on Figure B-5. Screening samples were analyzed on site for Ra-226, Cr, Pb and Hg. All of the screening sample results were below the SCs; therefore, no Phase II borings were drilled.

APPENDIX C

DESIGNATED-LEVEL SCREENING FOR DOMESTIC SEPTIC SYSTEMS

C. DESIGNATED-LEVEL SCREENING FOR DOMESTIC SEPTIC SYSTEMS

One of the primary remedial action objectives for the Laboratory for Energy-Related Health Research is to mitigate potential future impacts to ground water from residential constituents of concern (COCs) in United States Department of Energy (DOE) areas. To determine whether additional removal actions (RAs) may be needed to obtain this objective, a designated-level (DL) analysis was conducted for those domestic septic systems (DSSs) where no additional RAs are planned. DL analysis is a California State Water Resources Control Board process to evaluate whether soil contaminants have the potential to impact ground water.

To optimize data collection and lower cost, a phased approach was developed for DL sampling and analysis. The approach consists of first collecting and evaluating the confirmation analytical results to determine whether any COCs were present at the site above background. If needed, DL sampling would then be conducted to focus on specific COCs and hot spot areas. The DL approach approved by the LEHR Remedial Project Managers consists of:

- Preliminary DL analysis—Evaluate confirmation sampling results and identify DL COCs and potential hot spot areas.
- Data Gaps investigation—Collect additional data, if needed, for each DL COC at the potential hot spot area.
- Refined DL analysis—Model and calculate the DL values that protect ground water using a vertical profile of DL COCs.

Figure C-1 illustrates the preliminary DL analysis decision process that was conducted for Dry Wells A through E, Domestic Septic Tank (DST) 1, DSS 4, and DST 5 using confirmation sampling results. The preliminary DL analysis for Dry Wells A through E and DST 1, DSS 4, and DST 5 is presented below.

C.1 Preliminary Designated-Level Analysis

Confirmation sampling data were used to conduct the preliminary DL analysis. The confirmation data were validated according to Standard Operating Procedure 21.1 (WA, 2001). The number of confirmation samples were:

- Twenty-nine from Dry Wells A through E;
- Two from DST 1;
- Four from DSS 4; and,

- One from DST 5.

Confirmation samples were analyzed for 171 analytes each except for 9 of the dry well samples which were analyzed for metals only.

The preliminary DL analysis consisted of four steps described below.

C.1.1 Step 1—Detected Versus Non-Detected Analytes

In Step 1, analytes not detected are removed from the DL evaluation. Of the 171 total analytes, the number of analytes not detected in each area are as follows:

- A total of 128 were not detected in the Dry Wells A through E confirmation samples;
- A total of 131 were not detected in DST 1 confirmation samples;
- A total of 115 were not detected in DSS 4 confirmation samples; and,
- A total of 134 were not detected in the DST 5 confirmation sample.

The majority of non-detected analytes were semi-volatile organic compounds (SVOCs), volatile organic compounds (VOCs), and pesticides. The detected analytes in the dry wells, DST 1, DSS 4, and DST 5 confirmation samples are shown in Tables C-1, C-2, C-3, and C-4, respectively.

C.1.2 Step 2—Background Comparison

Dry Wells A through E, DST 1, DSS 4, and DST 5 confirmation samples were all collected from depths greater than four ft below ground surface (bgs). Confirmation results were compared to deep (greater than four ft bgs) background values for analytes whose concentration was found to vary with depth as determined in Appendix C of the *Work Plan for Removal Actions in the Southwest Trenches, Ra/Sr Treatment Systems, and Domestic Septic Systems Areas* (WA, 2000c). Confirmation results were compared to non-depth-specific background values for analytes whose concentration was not found to vary with depth. Background values were the 80% lower confidence limit on the 95th quantile determined from the depth-stratified or non-stratified background data (WA, 2000). As shown in Tables C-1 through C-4, most analytes were below or only slightly above background.

The background screening criterion was defined as 1.5 times the COC's background value based on a review of acceptable error margin in analytical measurements. A detection of 1.5 times background was not considered significantly above background. For organic compounds such as pesticides and VOCs where no background data were available, the reported detection limits were used for the comparisons.

Most of the detected analytes carried forward from Step 1 were screened out during the background comparison in Step 2 (Tables C-1 through C-4). The analytes with one or more concentrations significantly above background for each area were as follows:

- Dry Wells A through E—Hexavalent chromium, chromium, mercury, molybdenum, selenium, silver, cesium-137 (Cs-137), strontium-90 (Sr-90), and toluene;
- DST 1—Hexavalent chromium, gamma-chlordane, and toluene;
- DSS 4—Hexavalent chromium, chromium, lead, mercury, selenium, zinc, alpha-chlordane, gamma-chlordane, Cs-137, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, pyrene, methylene chloride, and toluene; and,
- DST 5—Hexavalent chromium, uranium-235, and toluene.

C.1.3 Step 3—Chemical and Physical Properties

Step 3 of the preliminary DL data analysis consisted of comparing the chemical and physical properties that would significantly influence the fate and transport mechanisms of the analytes in the environment and predict their potential impact to ground water. Specifically, the soil adsorption coefficient (K_d) and the radiological decay half-life were used. Tables C-1 through C-4 present the K_d and radiological decay half-life values for the analytes detected above background.

K_d values, which represent the relative capacity for a compound to sorb to the surface of a soil particle versus water, were based on data in the following references:

- “Superfund Chemical Data Matrix (SCDM)” (US EPA, website); and,
- “Soil Screening Guidance for Radionuclides: Technical Background Document” (US EPA, 2000).

The smaller the K_d value, the less sorptive (or more mobile) the analyte. For this analysis, the lowest reported K_d value from the literature references for the analyte was selected to be conservative.

During previous site-specific vadose zone Non-Isothermal Unsaturated Flow and Transport (NUFT) modeling, K_d values for specific organic compounds were correlated to the time for the peak concentration to occur at the water table (time-to-peak). A significant correlation was observed during the site-specific modeling, and thus the K_d criterion was selected based on an acceptable time-to-peak for organic compounds. For example, a K_d of 10 milliliters per gram (ml/g) would be equivalent to 2,000 years for the analyte to reach the water table at the peak concentration. A K_d of 1,000 ml/g, corresponds to a time-to-peak of about 100,000 years.

The K_d values for pesticides, SVOCs, and VOCs were compared to a K_d of 10 ml/g. The K_d values for inorganics, such as metals and radionuclides, which are typically less mobile, were compared to a K_d of 1,000 ml/g. Those constituents with K_d values exceeding these criteria were screened out of the DL analysis, based on the extremely long expected peak times (>2,000 years for SVOCs/VOCs and >100,000 years for metals/radionuclides).

Hexavalent chromium and all of the metals and radiological analytes evaluated in Step 3 (except Cs-137 in DSS 4) had K_d values less than the screening limits (Tables C-1 through C-4) and were potentially less sorptive (or more mobile). The more sorptive (or less mobile) analytes that were screened out because their K_d exceeded the screening value were as follows:

- Dry Wells A through E—None;
- DST 1—Gamma-chlordane;
- DSS 4—Alpha-chlordane, gamma-chlordane, Cs-137, anthracene, benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, phenanthrene, and pyrene; and,
- DST 5—None.

The decay half-lives for the radionuclides detected at the site were selected from the same sources as for the K_d s listed above.

A screening criterion of less than one year was chosen for half-life comparison based on the disposal history. Since land disposal activity at the site ceased at least 20 years ago, and given that the maximum activities of radionuclides at LEHR were on the order of milliCuries, radionuclides with half-lives of one year or less should not significantly impact the ground water.

None of the half-lives for the radiological analytes evaluated in Step 3 are one year or less. All of the radiological analytes evaluated in Step 3 except Cs-137 were carried forward to Step 4. Cs-137 was screened out in Step 3 based on its K_d value and not due to its half-life, which is 30.2 years. The results of Step 3 are shown in Tables C-1 through C-4.

C.1.4 Step 4—Wilcoxon Rank Sum Test and Biodegradability Evaluation

The Wilcoxon Rank Sum (WRS) test statistically measures the relative similarity between the background data set and the cleanup unit data set, and is used to indicate whether the confirmation data distribution is statistically similar to the background distribution. To perform this test, a minimum number of samples must be available in both the background and cleanup unit data sets to provide reliable test results. The WRS test could not be conducted for the DST 1 and DST 5 cleanup unit because two and one samples, respectively, were collected. The WRS test was carried out for Dry Wells A through E and DSS 4 analytes, which had 29 and 4 samples, respectively, in their cleanup unit data sets.

The WRS test results are shown in Tables C-1 and C-3. The WRS test results for Dry Wells A through E analytes found the following:

- Hexavalent chromium, mercury, silver, and Sr-90 sample data were above the background distribution. However, Dry Wells A through E data were not sufficient in number to demonstrate low probability that the test results were in error for these analytes.
- Chromium data were above the background distribution and the Dry Wells A through E data were sufficient to demonstrate low probability of erroneous test results.
- Selenium data were not above the background distribution and the Dry Wells A through E data were nearly sufficient (30 data points needed, 29 available) to demonstrate low probability of erroneous test results.

The WRS test results for DSS 4 analytes indicated that hexavalent chromium, chromium, lead, mercury, and selenium were above the background distribution, and zinc was not above the background distribution. However, DSS 4 data were not sufficient in number to demonstrate low probability of erroneous test results for any of the analytes.

The only organic analytes evaluated in Step 4 were methylene chloride and toluene. The WRS test is not applicable to these organic analytes because they are assumed to have zero concentration in background soil and therefore no background distribution.

Toluene was screened out during Step 4 for the Dry Wells A through E, DST 1, DSS 4 and DST 5 because it is readily biodegradable in soil. Methylene chloride was carried forward in the DSS 4 evaluation because it is biologically recalcitrant. The Step 4 screening results are shown in Tables C-1 through C-4.

C.1.5 Preliminary Designated-Level Analysis Conclusions

The preliminary DL analysis identified hexavalent chromium and various metals and radiological analytes as DL COCs (Tables C-1 through C-4). Specifically, the DL COCs for each area were as follows:

- Dry Wells A through E—Hexavalent chromium, chromium, mercury, molybdenum, silver, Cs-137, and Sr-90.
- DST 1—Hexavalent chromium.
- DSS 4—Hexavalent chromium, chromium, lead, mercury, and selenium. Methylene chloride was dropped from the list of DL COCs because it is a common laboratory contaminant that frequently causes false-positive results and was detected only once in the DSS 4 samples.
- DST 5—Hexavalent chromium and uranium-235.

Notes

- ⁽¹⁾ DOE-established background value for naturally occurring analytes in soil located at depths below 4 feet below ground surface, represents the 80% lower confidence limit on the 95th percentile based on background sample results. Detection limit used for pesticides, VOCs and SVOCs.
- ⁽²⁾ Results are considered significant enough to require further screening if maximum concentration is greater than 1.5 times background and more than 5% of the data are above background.
- ⁽³⁾ Limit Kd is 1,000 ml/g for inorganic compounds and 10 ml/g for organic compounds (see text for explanation).
- ⁽⁴⁾ Insufficient data were available to demonstrate allowable decision error in WRS test results.
- ⁽⁵⁾ All background data are not detected; WRS test cannot be applied to analyte.
- ⁽⁶⁾ Noether data sufficiency calculation indicated 29.47 (rounded up to 30) selenium DW samples were needed to demonstrate decision errors were not exceeded in WRS test. Twenty-nine selenium DW data were used in test. Decision errors were not likely exceeded.

Notes

- ⁽¹⁾ Established background value for naturally occurring analytes in soil located at depths below 4 feet below ground surface. Detection limit used for pesticides, VOCs and SVOCs.
- ⁽²⁾ Results are considered significant enough to require further screening if maximum concentration is greater than 1.5 times background and more than 5% of the data are above background.
- ⁽³⁾ Limit K_d is 1,000 ml/g for inorganic compounds and 10 ml/g for organic compounds.
- ⁽⁴⁾ Insufficient DSS 4 data were available to demonstrate allowable decision error in WRS test results.
- ⁽⁵⁾ Zinc in DSS 4 soil will not likely have greater impact on ground water than background. However, the comparison between DSS 4 soil samples and background may have a high decision error.
- ⁽⁶⁾ Methylene chloride is a common laboratory contaminant that was detected only once in the samples. It is not likely present in DSS 4 soil.

APPENDIX D

AIR MONITORING

D. AIR MONITORING

This appendix summarizes all air monitoring data collected for the Laboratory for Energy-Related Health Research (LEHR) Federal Facility. This includes both monitoring of ambient conditions and monitoring during each removal action (RA).

D.1 Baseline Air Sampling Program

A one-year baseline air sampling program was implemented for the LEHR Site by Pacific Northwest National Laboratory (PNNL) in August 1995. The program included three site perimeter sampling stations, one background station, and one meteorological station. The goals of the program were to:

- Document background air concentrations for contaminants of concern;
- Support a quantitative risk assessment;
- Detect, characterize, and report unplanned releases;
- Verify effluent treatment and control programs;
- Identify potential environmental problems and evaluate the need for remedial actions;
- Assess airborne impacts during remedial actions;
- Establish local meteorological conditions; and,
- Verify compliance with applicable federal, state, and local regulations and DOE orders.

Airborne contaminants were sampled by a network of four continuously operating samplers: three samplers on or near the site perimeter (AM-2, AM-3, and AM-5) and one sampler at a distant location (Figure D-1). The on-site meteorological station provided measurements of wind speed, wind direction, temperature, and barometric pressure. Hourly-average measurements were recorded with an automated data acquisition system. Other meteorological data were collected from the University of California, Davis Climatological Data Center, located approximately one mile northwest of the Site.

Radionuclide monitoring included continuous air monitoring for tritium and for particle-associated radionuclides. Airborne particles were sampled by continuously drawing air through a high-efficiency glass-fiber filter. Filters were collected every two weeks and analyzed for total beta and total alpha radioactivity. Quarterly composites of these biweekly samples were analyzed for the

gamma-emitting radionuclides cobalt-60 (Co-60), cesium-137 (Cs-137), and radium-226 (Ra-226), and other specific radionuclides, including isotopes of uranium, thorium, and strontium. Radon was sampled using passive alpha-track air sampling cartridges that were exchanged quarterly. Atmospheric water vapor was collected for tritium analysis by continuously passing air through cartridges containing silica gel, which were exchanged every four weeks.

Samples for chlordane, metals, volatile organic compounds (VOCs), and airborne dust analyses were collected at the same four sampling locations as those used for radiological air sampling. Twenty-four hour samples were collected in August 1995, September 1995, October 1995, January 1996, April 1996, and July 1996. The results for the baseline air monitoring program indicate that site air levels of the measured radionuclides, metals, VOCs, and chlordane are similar to those at the distant locations, and that all levels are well below DOE and/or US EPA standards (PNNL, 1996). The air data collected during the baseline program were not validated. Therefore, no statistical tests were done on this data set.

D.2 Wilcoxon Rank Sum and Sign Tests

Air data gathered at the LEHR Site did not fit the parametric assumptions of normal or lognormal distributions; thus the standard student's *t* test was not appropriate to evaluate these data. The Wilcoxon Rank Sum (WRS) and Sign tests were utilized to perform nonparametric statistical analyses on the data. These two tests were applied according to data quantity for all constituents of concern (COCs) at the Site. COCs with sufficient data were analyzed by the WRS test, while COCs with low data quantities were analyzed by the Sign test. These tests are outlined in the Statistical Method for Evaluating the Attainment of Cleanup Standards, Vol. 3 (US EPA, 1994b).

The WRS test evaluates the null hypothesis that the probability distributions associated with the two populations (i.e., background data and perimeter data) are equivalent against the alternative hypothesis that one population probability distribution is shifted to the right or left. The WRS test, which measures the relative similarity between the background data set and the environmental sample population, is used to indicate whether the air monitoring data can be represented by the background distribution. In order to perform this test, at least 40% of the data set should be values detected above the detection limit (US EPA, 1994b).

The WRS test calculates a statistic known as the Z_{rs} value, which is based on error parameters. If the calculated Z_{rs} value is greater than the acceptable $Z_{1-\alpha}$ value from a look-up table, then the COC passes the WRS test background comparison, and vice versa. Minimum error parameters were not provided for the Remedial Investigation/Feasibility Study air monitoring statistics; therefore, Weiss Associates (WA) used the error parameters discussed with and approved by the US EPA to develop risk-based action standards (RBASs).

Two types of decision errors can be made when a statistical test is performed on environmental data:

- A Type I Error occurs when the test incorrectly indicates that the cleanup standard has been achieved. The maximum allowed probability of a Type I error is denoted by alpha (α). An α value of 0.1 was used for the air monitoring WRS test.
- A Type II Error occurs when the test incorrectly indicates that the cleanup standard has not been achieved. The allowed probability of a Type II error is denoted by beta (β). A β value of 0.2 was used for the air monitoring WRS test.

Data sets with less than 40% of the values above the detection limit were evaluated with the Sign test. The Sign test is specifically designed to test hypotheses about the median of any population. The Sign test comparison was categorized into three regulatory risk guidelines depending on which value was available for each COC:

- US EPA Region 9 Preliminary Remediation Goal (PRG) ambient air value (if available)—The PRG values are health-based concentrations that correspond to either a one-in-one million (1E-06) cancer risk or a chronic health quotient of one, whichever is lower (PNNL, 1996);
- Occupational Safety and Health Administration (OSHA) permissible exposure limits (PELs)—The OSHA PELs are maximum air concentrations of specific constituents allowed to exposed workers based on a time-weighted averaged for an eight-hour workshift;
- Department of Energy (DOE) Derived Concentration Guide (DCG) for ambient air radionuclides—The DCG values represent the concentrations of radionuclides in air that an individual could continuously inhale and be immersed at average annual rates without receiving an effective dose equivalent to, or greater than, 100 millirems per year (PNNL, 1996).

D.3 Site Air Monitoring

Following the baseline air monitoring program, site air monitoring was conducted from October 30, 1996 to June 1998. Bimonthly monitoring for gross alpha and beta was conducted for that time period. Samples were also collected and analyzed for gamma emitters and radon. The statistical tests described in Section D.2 were run for all of the validated data with constituent concentrations greater than their respective detection limits.

D.3.1 Statistical Test Results

All of the analytical results for actinium-228, bismuth-212 (Bi-212), bismuth-214 (Bi-214), cesium-134 (Cs-134), Cs-137, Co-60, lead-214 (Pb-214), potassium-40 (K-40), thorium-208, and thorium-234 were below their detection limits. Twelve of 22 radionuclides were detected at concentrations above their respective detection limits (Table D-1). Of these, gross alpha, gross beta,

Ra-226, thorium-228 (Th-228), thorium-230 (Th-230), thorium-232 (Th-232), uranium-233/234 (U-233/234), and uranium-238 (U-238) were detected in over 85% of the samples collected. Additionally, Th-228, Th-230, Th-232, U-233/234, and U-238 were detected in concentrations above their respective detection limits in all samples.

WRS tests were run on the gross alpha, gross beta, Ra-226, Th-228, Th-230, Th-232, U-233/234, and U-238 data sets. The WRS test was used to compare all of the data collected on site to the data collected from the background air monitoring station. The WRS test determined that the data collected from the on-site air monitoring stations were statistically identical to the background air monitoring station data for these parameters.

Radionuclides that were detected sporadically included: lead-210 (Pb-210), lead-212 (Pb-212), strontium-89/90 (Sr-89/90), and uranium-235 (U-235). Sign tests were conducted on the Pb-210, Pb-212, Sr-89/90, and U-235 data sets. Sign test results indicated that the median of the Pb-210, Pb-212, Sr-89/90, and U-235 data sets were below established DCG values. All radon results were below the DCG limit of 3.0 picoCuries per liter.

Th-228 and U-233/234 had maximum concentrations of 1.83E-16 microCuries per milliliter ($\mu\text{Ci/ml}$) and 1.07E-16 $\mu\text{Ci/ml}$, respectively. DCG values for Th-228 and U-233/234 are 4.0E-14 $\mu\text{Ci/ml}$ and 9.0E-14 $\mu\text{Ci/ml}$, approximately two orders of magnitude higher than the maximum detected concentrations. Gross alpha and gross beta do not have assigned DCG values. The maximum detected concentrations of all of the other radionuclides were below their respective DCG values. The maximum and average radionuclide air concentrations, DCGs and statistical test results are shown on Table D-1. The data set suggest that the radionuclide concentrations in ambient air at the LEHR Site between October 30, 1996 and June 1998 did not pose any significant health risks to site workers or laboratory personnel.

D.4 Western Dog Pens Removal Action Air Monitoring

Based on the COCs detected in soil at the Western Dog Pens (WDPs) area prior to the 2001 RA, the following RA air monitoring program was established: pre-, post-RA sampling and monthly sampling for Ra-226, Sr-90, chlordane and particulate matter less than 10 microns in diameter (PM_{10}). Table D-2 presents the average and maximum concentrations, PELs, PRGs, DCGs and statistical test results for all of the constituents with concentrations greater than their detection limits.

D.4.1 Chlordane

Chlordane was detected at a concentration greater than the detection limit in one sample. The sign tests indicated that the median of the data set was below the PRG and PEL ambient air values. The only detected concentration, 0.158 micrograms per cubic meter ($\mu\text{g/m}^3$), was above the PRG, but well below the PEL.

D.4.2 PM_{10}

US EPA specifies a size-specific air quality standard for ambient air particulate. The standard applies to PM_{10} concentrations (Federal Register, 1987). PM_{10} concentrations did not exceed the $150 \mu\text{g}/\text{m}^3$ standard for any 24-hour period.

D.4.3 Ra-226 and Sr-90

Sr-90 was not reported above the detection limit in any of the air samples collected during the WDPs RA. Ra-226 was detected above the detection limit in seven of 20 samples at concentrations ranging from $5.38\text{E-}17$ to $6.94\text{E-}15 \mu\text{Ci}/\text{ml}$. The sign tests indicated that the median of the data set was below the DCG. The maximum concentration was well below the DCG.

D.4.4 Conclusion

On-site air monitoring data collected during the WDPs RA indicated that ambient air concentrations did not pose any health risks to site workers or laboratory personnel at LEHR.

D.5 Southwest Trenches Removal Action Air Monitoring

Based on the COCs detected in soil at the Southwest Trenches (SWT) area prior to the 1998 RA, the following RA air monitoring program was established: pre- and post-RA sampling for gamma emitters; monthly sampling for metals, VOCs, pesticides and gross alpha and beta; and, periodic sampling for tritium. Tables D-3 and D-4 present the average and maximum concentrations, PELs, PRGs and statistical test results for all of the constituents with concentrations greater than their detection limits.

D.5.1 Metals/Inorganics

Only eight metals were detected at concentrations greater than their detection limits (Table D-3). All the metal species passed their respective WRS or Sign tests. There was no statistical difference between the on-site and background data for the constituents that passed the WRS test (Table D-3). The Sign test indicated that the medians of the data sets were below their PRG or PEL ambient air values. Metal species such as calcium, copper, iron, magnesium, sodium and zinc did not have a PRG for ambient air values, but all passed the Sign test when evaluated using PEL values.

D.5.2 Pesticides

Three pesticides were detected at concentrations greater than their detection limits: 4,4-DDE, chlordane and heptachlor (Table D-3). 4,4-dichlordiphenyl ethylene (DDE) was detected in one sample at a concentration of $3.37\text{E-}04 \mu\text{g}/\text{m}^3$, which is approximately two orders of magnitude lower than the established PRG value. Chlordane and heptachlor were detected in two samples with maximum concentrations of 0.257 and $0.0016 \mu\text{g}/\text{m}^3$, respectively. Both chlordane and heptachlor maximum concentrations were slightly above their respective PRG values, $0.019 \mu\text{g}/\text{m}^3$ (chlordane) and $0.0015 \mu\text{g}/\text{m}^3$ (heptachlor), but well below the OSHA PEL of $500 \mu\text{g}/\text{m}^3$ for both compounds.

D.5.3 Volatile Organic Compounds

The majority of the VOCs were below their detection limits. Ten of the 20 VOCs detected had a frequency of 12 detections or more in the SWT air monitoring samples (Table D-3) where WRS statistical tests were conducted. The WRS test indicate that there is no statistical difference between the on-site air data and the background air data for 1,4-dioxane, acetone, benzene, bromomethane, chloromethane, ethanol, freon-12, methylene chloride, toluene, trichlorofluoromethane and xylenes. The average and maximum concentrations of these compounds were also below PRG and OSHA PEL values. Benzene and 1,4-dioxane were the only VOCs that exceeded their PRG values. Although the on-site benzene and 1,4-dioxane concentrations were often higher than the PRG values for ambient air, the WRS test determined that the benzene and 1,4-dioxane concentrations detected in on-site air samples were statistically identical to the background air concentrations. Sign tests were conducted on the data sets of the remaining detected compounds. Sign test results indicated that the medians of the VOC data sets were below their respective PRG and/or PEL concentrations (Table D-3).

D.5.4 Radionuclides

A total of ten radiological parameters were detected in concentrations above their detection limits. Table D-4 presents the average and maximum concentrations, DCGs and statistical test results for all of the radionuclides with concentrations greater than their detection limits. There were no radionuclides detected at concentrations that exceeded their established DCG values.

All the radionuclides detected passed their WRS tests indicating that there is no statistical difference between the median of their data sets and the background data (Table D-4).

D.5.5 Conclusion

On-site air monitoring data collected during the SWT RA indicated that ambient air concentrations did not pose any health risks to site workers or laboratory personnel at LEHR.

D.6 Radium/Strontium Treatment Systems Removal Actions Air Monitoring

As discussed in Section 2.4.1, the Radium/Strontium (Ra/Sr) Treatment Systems RA was conducted in 1999 and 2000. During the 1999 Ra/Sr Area I RA, Domestic Septic Tank 2, a distribution box, piping, three dry wells, and the Northern and Southern Leach Trenches were removed. The Ra/Sr Treatment Systems Area I air monitoring program included pre- and post-RA sampling for chlordane, tritium, VOCs, gross alpha and beta, gamma emitters, PM₁₀ and metals, and monthly monitoring for gross alpha and beta. During the Ra/Sr Treatment Systems Area II RA, the Ra-226 Tank, the Sr-90 Tank, the Sr-90 Tank Leach Field and the influent tank piping were removed. The Ra/Sr Treatment Systems Area II air monitoring program included pre- and post-RA sampling for gross alpha and beta, Sr-90, gamma emitters, PM₁₀ and metals; and monthly sampling for gross alpha and beta, Sr-90, gamma emitters and PM₁₀. The monitoring programs were designed to monitor each area for potential releases of known COCs to ambient air as a result of RA activities.

D.6.1 Pesticides

Only one of 21 pesticides was detected at concentrations greater the detection limits during the Ra/Sr RAs. 4,4-DDE was detected in two samples at a maximum concentration of 5.6E-04 µg/m³, which is approximately two orders of magnitude lower than the established PRG of 2.0E-02 µg/m³.

D.6.2 Volatile Organic Compounds

The majority of the VOC concentrations detected in air during the Ra/Sr Treatment Systems RAs were below their detection limits. Acetone, benzene, chloromethane, ethanol, freon-12, toluene, and trichloroflouromethane were the most frequently detected VOCs in Ra/Sr Treatment Systems RA air monitoring samples. Table D-5 presents the average and maximum concentrations, PELs, PRGs and statistical test results for all of the constituents with concentrations greater than their detection limits.

The WRS tests indicate that there is no statistical difference between the on-site air data and the background air data for acetone, 2-butanone, bromomethane, chloromethane, ethanol, freon-12, methylene chloride, toluene, trichloroflouromethane and m,p-xylenes. The average and maximum concentrations of these compounds were also below PRG and OSHA PEL values. Benzene and 1,4-dioxane were the only two VOCs that exceeded their PRG values. Although the on-site benzene and 1,4-dioxane concentrations were often higher than the PRG values for ambient air, the WRS test determined that the benzene and 1,4-dioxane concentrations detected in on-site air samples were statistically identical to the background air concentrations. Sign tests conducted on the data sets of the remaining detected compounds indicated that the median values of the VOC data sets were below their respective PRG and/or PEL concentrations (Table D-5).

D.6.3 Metals/Inorganics

All of the metals included in the analytical suite were identified above their detection limits in at least one of the on-site air samples. However, the majority of the metal concentrations measured in ambient air were below their detection limits. Table D-5 presents the average and maximum concentrations, PELs, PRGs and statistical test results for all of the metals with concentrations greater than their detection limit.

All of the metal species, with the exception of chromium, passed their respective WRS or Sign tests. There was no statistical difference between the on-site and background data for the constituents that passed the WRS test (Table D-5). The Sign test indicated that the medians of the data sets, with the exception of chromium, were below their PRG or PEL ambient air values. Arsenic, beryllium, cadmium and chromium had mean concentrations that were above their respective PRG values; however, the mean and maximum concentrations were well below the established OSHA PEL values. Metal species such as antimony, cobalt, selenium, silver, thorium, and vanadium did not have PRGs for ambient air values, but all passed the Sign test when evaluated using PEL values.

D.6.4 Radionuclides

A total of eight radionuclides in addition to gross alpha and gross beta were detected at concentrations above their detection limits. Of these, only Cs-137, gross alpha, gross beta and K-40 were detected more than once and gross alpha and gross beta were detected in over 50% of the samples collected. Table D-6 presents the average and maximum concentrations, DCGs and statistical test results for all of the radionuclides with concentrations greater than their detection limit.

There were no radionuclides detected at concentrations that exceeded their established DCG values. Statistical evaluations were performed on all of the radionuclides with concentrations above their detection limits. In the cases where Sign tests were required, the tests were run using the DCG value from lung retention class "Y" which represents a removal half-time of 500 days. Bi-214, Cs-137, Pb-210, Pb-212, and K-40 did not have an assigned DCG value for retention class Y, so their Sign tests were run using the values from retention classes W and D, which represent removal half-times of 0.5 and 50 days, respectively.

Gross alpha and gross beta do not have established DCGs but these parameters passed their WRS tests indicating that there is no statistical difference between the median of their data sets and the background data. Actinium-228, Bi-212, Cs-134, Pb-214, radium-223, radium-228, Sr-90, thallium-208, and U-235 were not reported at concentrations above their detection limits; therefore, statistical tests could not be run for these constituents. All of the radionuclide data sets passed their respective Sign and WRS tests.

D.6.5 PM₁₀

PM₁₀ concentrations are not to exceed the US EPA 150 µg/m³ standard for a 24-hour period. PM₁₀ concentrations exceeded the air quality standard only once on June 22, 1999, when an on-site air monitoring station had a concentration of 165.2 µg/m³.

D.6.6 Conclusion

On-site air monitoring data collected during the Ra/Sr Treatment Systems RAs indicated that ambient air concentrations did not pose any health risks to site workers or laboratory personnel at LEHR.

D.7 Domestic Septic Systems 3 and 6 Removal Actions Air Monitoring

Based on the COCs detected in soil at the DSS areas prior to the 2002 RA, air sampling was conducted once during RA activities to monitor for potential releases of barium, cadmium, Cs-137, chlordane, chromium, copper, heptachlor epoxide, lead, Pb-210, Hg, Ra-226, silver, Sr-90, and PM₁₀ into ambient air.

D.7.1 Analytical Results

Since there was only one sampling event, there were not adequate data to perform statistical tests on the analytic data. The average air concentrations from the three air monitoring stations on site were calculated and compared to the concentrations detected at background station AM-3 (Figure D-1). Chlordane, silver and heptachlor epoxide were not reported at concentrations greater than their detection limits and therefore were not included in this evaluation. All of the other average air concentrations, with the exception of Cs-137 and chromium, were above background (Table D-7). All of the maximum detected air concentrations were then compared to the appropriate regulatory limits. All radionuclide air concentrations were below their respective DCGs. All metals air concentrations were below their respective PRGs and PELs, with the exception of chromium. Chromium exceeded its PRG for ambient air, but was well below the OSHA PEL.

The US EPA specifies a size-specific air quality standard for ambient air particulates that applies to PM₁₀ concentrations (Federal Register, 1987). PM₁₀ concentrations did not exceed the 150 micrograms per cubic meter standard for a 24-hour period. The highest recorded PM₁₀ concentration for the DSS RA was 20.6 µg/m³ for a 24-hour period.

On-site air monitoring data collected during the DSS 3 and 6 RAs indicated that ambient air concentrations did not pose any health risks to Site workers or laboratory personnel at LEHR.

Strontium-90	µCi/ml	3.62E-17	4.94E-17	ND	9E-12	N/A	N/A	Yes	No

Notes

- ¹ The background concentration is the air concentration detected at background air monitoring station AM-3 during the Domestic Septic Systems 3 and 6 removal actions.
- ² Regulatory limit refers to derived concentration guides for radionuclides and preliminary remediation goals/ permissible exposure limits for metals.
- ³ The left side states whether the maximum concentration is greater than the preliminary remediation goal. The right side states whether the maximum concentration is greater than the permissible exposure limit.
- ⁴ Derived concentration guide value for lung retention class “D”.
- ⁵ Preliminary remediation goal for elemental mercury.
- ⁶ Mercury (aryl and inorganic compounds).
- ⁷ Derived concentration guide value for lung retention class “W”.

Abbreviations

- DCG derived concentration guide
- N/A not applicable
- ND not detected
- PEL permissible exposure limit
- PRG preliminary remediation goal for ambient air
