APPENDIX F

DOE BOX DATA EVALUATION

F. DOE BOX AND DRY WELLS A THROUGH E DATA EVALUATION

The United States Department of Energy (DOE) Box Data Evaluation was completed after all analytical results from the confirmation sampling were received. During the Phase II Data Evaluation, confirmation sampling results were tabulated according to chemical group, and then human health risk and designated-level (DL) analyses were conducted.

A human health risk analysis was conducted on the Dry Wells A through E (DWs A through E) area. Since no formal confirmation sampling was conducted at DWs A through E, the risk analysis was conducted on all of the data that represent current conditions at this area. The DL analysis for this area is presented in Appendix C.

The human health risk analyses were used to 1) determine whether the potential excess cumulative cancer risk to an individual from exposure to residual contamination at the DOE Box area is within a nominal range of 10^{-4} to 10^{-6} , using 10^{-6} as the point of departure; 2) determine whether the potential cumulative non-cancer risk-based action standard (RBAS) hazard quotient (HQ) is below 1. The DL analysis was conducted to assess the potential future impacts to ground water. The first steps in the DOE Box Data Evaluation were data management and validation, as described below.

The human health risk analyses for the other DOE areas has been included in the following reports: *Final Western Dog Pens Area Removal Action Confirmation Report* (WA, 2002a), *Final Radium/Strontium Treatment Systems Area Removal Action Confirmation Report* (WA, 2002b), *Draft Domestic Septic Systems 3 and 6 Removal Actions Confirmation Report* (WA, 2002c), and *Final Southwest Trenches Area 1998 Removal Action Confirmation Report* (WA, 2001).

The constituents of concern (COCs) included in the human health risk analyses discussed below were identified based on historical release information, characterization data and statistically-based background comparisons using US EPA protocols. The Site-Wide Risk Assessment (SWRA) will identify the final COCs for the DOE and UC Davis areas. The DOE Areas Feasibility Study Report will document any changes to COCs identified for the DOE Box and DWs A through E area.

F.1 Data Reduction/Verification/Reporting and Records Management

Obtaining valid and comparable data requires adequate quality assurance/quality control (QA/QC) procedures and documentation. The QA requirements applicable to the removal action (RA) activities are provided in the Final Quality Assurance Project Plan (QAPP) (Weiss Associates [WA], 2000a). The QAPP is based upon the requirements of DOE Order 5700.6c "Quality Assurance" and QAMS-005/80 (United States Environmental Protection Agency[US EPA], 1980)

“Interim Guidelines and Specifications for Preparing Quality Assurance Project Plans” as they are applicable to the RA scope of work.

Per the QAPP and DOE Box Area Work Plan, the following activities were conducted to ensure data usability:

- Sample collection QA/QC;
- Data reduction, verification, reporting, and validation; and,
- Data management.

F.1.1 Sample Collection Quality Assurance/Quality Control

Field QA/QC samples were collected according to procedures to ensure reliability of field sampling procedures and materials. Three field duplicates, 10% of the 30 DOE Box area confirmation samples, and 1 equipment rinseate blank were collected following the RA, as required in the QAPP and Work Plan. The relative percent difference for the limited suite analytes (cadmium, chromium, mercury, hexavalent chromium, nitrate) ranged from 0 to 184%.

Sampling at the DW A through E area was conducted in 1997, 1999 and 2001. In 1997, four samples were collected (no field duplicates) were collected from the area. In 1999, eleven samples (including one field duplicate) were collected from the DW A to E area. Two of these eleven samples were removed during the limited removal action that was conducted in this area, and therefore, not included in the risk screening. In 2001, 32 investigation samples (including four field duplicates) were collected from the DWs A through E. Since there were no driver constituents of concern (COCs) for the DWs A through E area, no relative percent differences were calculated.

F.1.2 Data Reduction, Verification, Reporting, and Validation

Accurate data reduction, validation, and reporting protocols are necessary to interpret data and make sound decisions. After the DOE Box closure sampling and DWs A through E sampling were completed, data reduction, verification, reporting, and validation were performed, as required by the QAPP and respective Work Plans.

Independent of the laboratory review, WA performed data validation and verification on the analyzed samples using the "US EPA Contract Laboratory Program National Functional Guidelines for Organic Data Review" (US EPA, 1988a) and "US EPA Contract Laboratory Program National Functional Guidelines for Inorganic Data Review" (US EPA, 1988b). Analytical results were qualified as a result of the data validation process in accordance with the flagging convention described in the QAPP.

Sample results and associated QA/QC results that were reviewed included (as applicable): holding times, field and laboratory blank results, laboratory control sample spike results, matrix spike/matrix spike duplicate recovery failure (m qualifier), laboratory matrix duplicate results,

surrogate recoveries and internal standard performance. All sample results were identified as usable (no qualifier), estimated and usable (with J or UJ qualifier), or rejected and unusable (with R qualifier). Rejected data and data containing substantial untraceable omissions or errors were removed from the database before determining the COC concentration terms. None of the DOE Box confirmation data or DWs A through E area data were rejected with an R qualifier.

F.1.3 Data Management

All electronic records were compared with the laboratory hard copy results to assure electronic database quality. Differences between electronic records and hard copy results were documented and resolved by investigating the validated data packages. Electronic records that contained errors were corrected and the corrections were documented and stored with the data validation records and detailed data packages. No errors were found on the hard copy results. The constituents that were detected in at least one DOE Box closure sample, but were not included in the risk analysis because they do not have RBAS values are: actinium-228, arsenic, beryllium, cobalt, iron, lead-212, nickel, nitrate, potassium-40, Radium-228 (Ra-228), thallium-208, thorium-230, uranium-233/234 and uranium-238 and vanadium. The constituents that were detected in at least one Dry Well A through E sample, but were not included in the risk analysis because they do not have RBAS values are: actinium-228, arochlor-1254, arsenic, bismuth-212, bismuth-214, beryllium, bromodichloromethane, bromoform, carbon Disulfide, chlorobenzene, chlorodibromomethane, chloroethane, chloroform, cobalt, 1,2-dichloropropane, cis-1,3-Dichloropropylene, 1,1-dichloroethane, 1,1-dichloroethene, 1,2-dichloroethane, 1,2-dichloroethene (total), iron, lead-212, lead-214, nickel, nitrate, potassium-40, Radium-228 (Ra-228), thallium-208, thorium-230, 1,1,1-trichloroethane, 1,1,2,2-tetrachloroethane, tetrachloroethylene, trans-1,3-Dichloropropene, 1,1,2-trichloroethane, trichloroethene, uranium-233/234, uranium-238, vanadium, and vinyl chloride. The upcoming Site-Wide Risk Assessment will address all positive detections from the DOE Box and DWs A through E area data sets.

Some COCs were reported below laboratory detection limits for the confirmation samples. Per the Environmental Regulatory Guide for Radiological Effluent Monitoring and Environmental Surveillance (DOE, 1991) and Statistical Methods for Environmental Pollution Monitoring (Gilbert, 1987), the data were managed as follows:

- All radionuclide results were used in statistical tests and sample statistic determinations including negative values, zero values and results below the minimum detectable activity. All radiological data were used to avoid bias in the statistical tests, concentration term calculations used in the risk screening, and sample statistics (Gilbert, 1987; DOE, 1991).
- For non-radionuclides, only values above the laboratory/contract-required detection limit or analytical method detection limit were used to calculate the concentration terms for the risk screening (Gilbert, 1987).

F.1.4 Data Summary

Analytical results were compared to RBAS values in Table 4-1. Notable findings based on review of the DOE Box closure sampling data include:

- All semi-volatile organic compounds, volatile organic compounds, pesticides and polychlorinated bi-phenyls results were below their detection limits.
- All of the DOE Box closure sample results were below their respective federal PRGs (California-modified PRG for lead).

Notable findings based on review of the DWs A through E sampling data include:

- All semi-volatile organic compounds were below their detection limits.
- All constituents that were statistically above background, were below their respective federal PRGs (California-modified PRG for lead).

F.2 Risk Screening

The risk screening conducted for this report evaluated potential impacts to human health at the three receptor locations shown in Figure F-1. A risk-screening evaluation was conducted using RBAS values developed for the Site (Section 4.3). The purpose of the risk screening was to determine if excess cancer risk was within the US EPA acceptable range of 10^{-4} to 10^{-6} and if non-carcinogenic effects were less than the cumulative hazard quotient (HQ) of 1.0. All of the constituents that were measured above the detection limit and had established RBAS values were included in the risk screening.

F.2.1 Background Concentrations

Background concentrations of COCs in LEHR-area soil (Table 4-1) were calculated using analytical results of off-site soil samples and US EPA-approved statistical methods. This evaluation used background concentrations presented in Appendix C of the Radium/Strontium Treatment Systems Work Plan (WA, 2000b). Specifically, the 80% lower confidence limit of the 95th quantile for the available off-site soil data was selected to represent the background value for each COC.

All of the DOE Box closure samples and DWs A through E samples were collected at depths greater than four feet below ground surface (ft bgs). Therefore, the background concentrations calculated for soil greater than four ft deep were used for the background comparisons during the data evaluations.

F.2.2 Risk-Based Action Standards

RBASs for the DOE areas at the LEHR site were developed and presented in the Draft Final Determination of Risk-Based Action Standards report (WA, 1997). The RBAS values are site-specific concentrations that yielded the target incremental cancer risk or non-cancer risk for each COC. DOE and the regulatory agencies use the RBAS values as cleanup guidelines during RAs.

The RBAS values are single COC concentrations which, if present in soil in DOE areas of the LEHR site, might result in the specified maximum individual excess cancer risk level (or HQ) to an exposed individual. RBAS values were developed using US EPA guidance for developing risk-based PRGs using a back-calculation approach for both carcinogenic and non-carcinogenic COCs.

The RBAS values were calculated using the following steps (WA, 1997):

- Identifying the COCs present in soil media in the DOE areas of the LEHR Site. Seventy-four chemicals and radionuclides were identified as LEHR Site COCs. All of the COCs with analytical results above the detection limit and an established RBAS were included in the risk screening;
- Identifying possible exposure pathways and scenarios;
- Conducting fate and transport modeling to relate on-site concentrations of the COCs to concentrations in exposure media;
- Calculating the chemical dose or intake for each COC; and,
- Performing iterative back-calculations to determine the source soil concentration or RBAS that yielded the acceptable incremental cancer or non-cancer risk.

For carcinogenic compounds, the RBAS values used in this risk screening are based upon a level of protection equal to the excess upper bound lifetime cancer risk of 10^{-6} . For systemic non-carcinogenic compounds, the RBAS values are equivalent to an HQ of 1.0, representing no significant adverse effect during a lifetime.

Risk assessments evaluate excess or incremental risk due to the presence of contaminants above background or naturally occurring contaminant levels. Background is typically identified as contributing zero excess or incremental risk since the contaminants are present regionally and are often naturally occurring. For some of the COCs, the RBAS values are less than their background concentrations. In these cases, the action standard is set at background. Additionally, if a COC is detected at or below background levels, it was assumed that it does not contribute to excess or incremental risk and was removed prior to the risk screening.

Three risk exposure scenarios have been developed and RBAS values were calculated for each scenario (WA, 1997). The RBAS values for the 10^{-6} excess cancer risk level and HQ equal to 1.0 for the DOE Box and DWs A through E COCs under each risk scenario are presented in Table 4-1. Figure F-1 shows the locations of the receptors. Each scenario is described below.

- Scenario 1: On-Site Researcher—Represents potential on-site workers that may be exposed to source area soil through external radiation from radionuclides at or near the ground surface (for radionuclides only), ingestion, inhalation and dermal exposure.
- Scenario 2: East Side Residential Farmer—Represents potential off-site residential farmers that may be exposed to potentially impacted ground water, potentially impacted surface water (via recreational use), and via external radiation from radionuclides at or near the ground surface (for radionuclides only). Exposure is through inhalation of fugitive dust, soil ingestion, and consumption of agricultural foods that are potentially impacted by fugitive dust migration from the on-site source areas.
- Scenario 3: South Side Residential Farmer—Identical to Scenario 2 except that exposure to impacted ground water is not included, since ground water flow from potential on-site LEHR sources is away from this receptor location. Ground water contamination does not impact Putah Creek since ground water does not discharge to the creek.

F.2.3 Reasonable Maximum Exposure

US EPA guidance (US EPA, 1994) recommends using a reasonable maximum exposure (RME) for Superfund risk assessments. The RME is a conservative estimate of intake and is defined as the highest exposure that could reasonably be expected to occur for a given exposure pathway at a site. The RME accounts for inherent environmental media sampling uncertainty in the contaminant concentration.

Per US EPA (1994), statistical calculations were performed for each COC to determine the concentration terms. The statistical calculations included determining the mean, standard deviation, and the 95% upper confidence limit (UCL) on the mean of data. The 95% UCL is a statistical value that is often calculated for Superfund sites to conservatively compare the cleanup area or remediation unit data to a pre-determined level such as the RBAS.

The US EPA recommends that the 95% UCL be used as the concentration term, or RME, in Superfund assessments because of the uncertainty associated with the true average concentration at a site. Though sampling plans are developed to collect an adequate number of samples to characterize the contamination at a site, the true mean of the contamination data set is rarely known or available.

The 95% UCL provides reasonable confidence that the true site average concentration will not be underestimated. The 95% UCL is defined as a value that, when calculated repeatedly for randomly drawn subsets of a site's data, equals or exceeds the true mean for the Site's concentration 95% of the time. Therefore, the 95% UCL is used as the average concentration because it is an available statistical value as opposed to the true mean of the population which typically is not available.

The 95% UCL varies depending on the distribution of the data and the mean for the data set and is calculated for a normally distributed data set, using the following formula:

$$95\% \text{ UCL} = \bar{x} + t_{.05}(S/(N)^{1/2})$$

Where,

- \bar{x} = Mean of the data set
- $t_{.05}$ = Student t value for a one-tailed 95% confidence interval and the representative number of degrees of freedom
- S = Standard deviation of the data set
- N = Number of samples

Three COCs (barium, chromium and copper) have log-normally distributed confirmation data sets based on the background data sets. It is assumed, therefore, that the confirmation data sets for these three COCs are also log-normally distributed. The following log-normal formula is used to calculate the 95% UCL on the mean for these data sets:

$$95\% \text{ UCL} = e^{\bar{x} + 0.5s^2 + sH/(n-1)^{0.5}}$$

Where,

- e = Constant (base of the natural log, equal to 2.718)
- \bar{x} = Mean of the transformed data set
- s = Standard deviation of the transformed data
- H = H-statistic (from the table published in Gilbert, 1987)
- N = Number of samples

If less than ten samples¹ contain detectable concentrations, the maximum detected concentration was selected as the concentration term or RME for the risk screening. This was the case for 7 of the 22 DOE Box COCs and for 13 of 34 DWs A through E removal action COCs. Otherwise, the 95% UCL on the mean was calculated to determine the concentration term or RME for the COC, using US EPA procedures (US EPA, 1992). Tables F-2 and F-3 presents the RMEs for all COCs detected during the DOE Box area closure sampling and DWs A through E, respectively.

¹ Sampling data from Superfund sites have shown that data sets with fewer than 10 samples per exposure area provide poor estimates of the mean concentration (US EPA, 1992). Thus, the maximum concentration is selected to represent the data set.

F.2.4 Background Comparison

Background comparisons were performed for COCs with an RBAS less than the background value. For the DOE Box Area, background comparisons were conducted for barium, copper, lead, mercury, manganese and thorium-232. For the DWs A through E data, background comparisons were conducted for the same COCs and also for cadmium, lead-210, thorium-228 and thorium-232. Per US EPA (1994), these were performed by comparing the data set for the background off-site soil data to the confirmation sampling data set for each applicable COC. For VOCs, SVOCs, and pesticides/PCBs, where no background data exist, the reported detection limit was used for the comparison.

US EPA guidance recommends the Wilcoxon Rank Sum (WRS) and the Quantile tests to perform the background comparison. These tests are outlined in the Statistical Method for Evaluating the Attainment of Cleanup Standards, Vol. 3 (US EPA, 1994). The WRS test is used to determine whether the RA has uniformly attained the cleanup goal for a particular COC throughout the cleanup unit, whereas the Quantile Test is more appropriate to detect when an RA has failed in only a few areas within the cleanup unit.

For the DOE Box Area, the results of the WRS and Quantile tests from the background comparisons are summarized in Table F-1. All DOE Box COCs passed the WRS and Quantile tests with the exception of mercury. All of these COCs were eliminated from their respective risk screenings, since their confirmation data sets were similar to background and were therefore assumed not to contribute to excess or incremental risk at the site. The mercury data sets both failed the WRS and Quantile tests and histogram comparisons. The data suggest that mercury is present in concentrations above background for the Site. Accordingly, mercury was not removed from the DOE Box area risk screening.

For the DWs A through E data, cadmium, copper, lead and mercury failed the WRS and/or Quantile tests (Table F-4). These COCs were included in the risk screening.

F.2.5 Risk Calculation

The risk screening decision process is illustrated in Figure F-2. For each carcinogenic COC with an RBAS above the background concentration, the RME is divided by the RBAS at specified risk levels (10^{-6} , 10^{-5} , and 10^{-4}). The sum of the RME/RBAS ratios for all COCs with an RBAS above the background concentration are then computed for each of the three risk scenarios. The ratios were summed up for each risk scenario to determine if the cumulative ratio was less than 1.

A similar ratio is calculated for the cumulative HQ for non-carcinogenic COCs. The sums of the RME/RBAS ratios for the non-carcinogens were summed up to determine if they were less than 1.0.

Below is an example of the calculation method used for the RME to RBAS comparisons.

Individual COC

$$\frac{RME_1}{RBAS_{1Scenario_n}} = \text{ratio of RME to the RBAS for each scenario (n = Scenario 1, 2 or 3)}$$

where:

$$RME_1 = \text{RME for COC}_1$$

$$RBAS_1 = \text{RBAS for COC}_1, \text{ in Scenario n}$$

Cumulative Carcinogenic COCs

$$\text{cumulative ratio} = \sum \frac{RME_1}{RBAS_{1Scenario_n}} + \frac{RME_2}{RBAS_{2Scenario_n}} + \frac{RME_3}{RBAS_{3Scenario_n}} \dots + \frac{RME_m}{RBAS_{mScenario_n}}$$

Cumulative Non-Carcinogenic COCs

$$\text{cumulative ratio} = \sum \frac{RME_1}{RBAS_{1Scenario_n}} + \frac{RME_2}{RBAS_{2Scenario_n}} + \frac{RME_3}{RBAS_{3Scenario_n}} \dots + \frac{RME_m}{RBAS_{mScenario_n}}$$

Tables F-5 and F-6 shows the RME/RBAS ratios for each COC and each scenario at the 10^{-6} excess cancer risk level, and HQ = 1.0 non-carcinogenic risk level for the DOE Box closure sampling and DWs A through E sampling, respectively. Tables F-7 and F-8 show the cumulative RME/RBAS ratios for each scenario at the 10^{-6} , 10^{-5} , and 10^{-4} excess cancer risk levels and HQ = 1.0 non-carcinogenic risk level for the DOE Box and DWs A through E areas, respectively.

F.2.5.1 Cancer Risk Calculations

F.2.5.1.1 DOE Box Area

Comparison of the RBAS values to the measured soil concentrations indicates that none of the individual COCs exceed the carcinogenic RBAS values in the DOE Box area for the 10^{-6} , 10^{-5} , or 10^{-4} target risk levels. At 10^{-5} and 10^{-4} target incremental carcinogenic risk levels, the cumulative RME/RBAS ratio are below 1.0 for the DOE Box area. At a 10^{-6} risk level, the cumulative RME/RBAS ratio, 1.03, slightly exceeds 1.0.

Tables F-5 and F-7 show the DOE Box area individual carcinogenic COC RME/RBAS ratios and the cumulative carcinogen RME/RBAS ratios, respectively. These data demonstrate that the cumulative residual risk for carcinogens falls within the US EPA Comprehensive Environmental Response, Compensation and Liability Act risk range of 10^{-4} to 10^{-6} .

F.2.5.1.2 Dry Wells A through E Area

At DWs A through E, lead exceeded the 10^{-6} and 10^{-5} target risk levels for Scenario 1 and Scenario 2, respectively. For exposure Scenario 1, at 10^{-5} and 10^{-4} target incremental carcinogenic risk levels, the cumulative RME/RBAS ratio are below 1.0 for the DWs A through E area. For exposure Scenario 2, at 10^{-4} target incremental carcinogenic risk level, the cumulative RME/RBAS ratio is below 1.0. For exposure Scenario 2, the RME/RBAS ratio for lead accounted for 68.18 of 70.85 of the cumulative RME/RBAS ratio. However a histogram comparison of the DWs A through E lead data and the background data set show that the DWs A through E data is just slightly above background (Figure F-3). For exposure Scenario 3, the cumulative RME/RBAS ratio are below 1.0 for the 10^{-6} , 10^{-5} , or 10^{-4} target risk levels.

Tables F-6 and F-8 show the DWs A through E area individual carcinogenic COC RME/RBAS ratios and the cumulative carcinogen RME/RBAS ratios, respectively. These data demonstrate that the cumulative residual risk for carcinogens falls within the US EPA Comprehensive Environmental Response, Compensation and Liability Act risk range of 10^{-4} to 10^{-6} .

F.2.5.2 Non-Cancer Risk Calculation

F.2.5.2.1 DOE Box Area

Comparison of the RBAS values to the measured site soil concentrations indicates that only one COC, mercury, exceeds its non-carcinogenic RBAS value based on an HQ of 1.0. Tables F-5 and F-7 show individual non-carcinogenic COC RME/RBAS ratios and the cumulative non-carcinogen RME/RBAS ratio, respectively.

Scenario 2 (East Side Residential Farmer) is the only scenario with a cumulative HQ that exceeded 1.0. The cumulative HQ for Scenario 2 is 4.30 with mercury (Hg) the most significant contributor with a ratio of 3.95.

The Hg HQ was also above 1.0 at the DSS 3, DSS 6, Southwest Trenches and Radium and Strontium Treatment Systems Areas. Hg above an HQ of 1.0 at many areas of the LEHR site could be due to the conservative assumptions that ground water would be ingested under Scenario 2.

F.2.5.2.2 Dry Wells A through E

Cadmium, copper, Hg and silver had RME values that exceeded their respective non-carcinogenic RBAS values based on an HQ of 1.0. Tables F-6 and F-8 show individual non-carcinogenic COC RME/RBAS ratios and cumulative non-carcinogen RME/RBAS ratio, respectively.

Scenario 2 (East side Residential Farmer) is the only scenario with a cumulative HQ that exceeded 1.0. The cumulative HQ for Scenario 2 is 10.42 with Hg and silver contributing fractions of 3.64 and 3.61, respectively.

F.2.5.3 Comparisons of Preliminary Remediation Goals to Reasonable Maximum Exposure Values

The RME values for each COC were compared to the following action standards:

- Chemical Constituents—Residential PRGs established by US EPA Region 9 in October 2002; and,
- Radionuclides—Radionuclide PRGs established by US EPA Region 9 in May 29, 2002.

All COC RME values were at or below their respective residential soil PRGs.

F.2.6 Hot Measurement Analysis

A “Hot Measurement Analysis” (US EPA, 1994) was also performed to determine if any COC exceeded its respective upper limit concentration value. If so, then further evaluation or additional remedial action may be required, at least locally, for the areas with hot measurements, regardless of the outcome of the background comparisons using the WRS and Quantile tests or the risk screening analysis.

The hot measurement analysis is typically used in background comparisons in conjunction with the WRS and Quantile tests to help ensure that unusually large sampling data measurements receive proper attention regardless of the outcome of the WRS and Quantile tests. Due to the de-emphasis of high concentrations when grouped with the entire data set, the WRS and Quantile tests may indicate that the remedial action is complete even if a few very high concentrations are detected in the remediation area.

For this Phase II Data Evaluation, a hot measurement analysis was performed on all COCs regardless of whether they were included in the background comparison to determine if COC measurements exceeded a value equal to ten times their respective 10^{-6} RBAS values for the carcinogenic removal action COCs, and the RBAS for the non-carcinogenic COCs. A factor of ten times the 10^{-6} RBAS was selected since it would correspond to a 10^{-5} excess cancer risk level, or the middle of the US EPA target risk range. The non-carcinogenic RBAS values were treated differently because, in contrast to carcinogens which have risk levels from 10^{-6} to 10^{-4} , risk assessments typically use only one risk level for non-carcinogens: HQ = 1.0.

The results of the hot measurement analyses for the DOE Box area are presented in Table F-9. Mercury was the only COC that failed the hot measurement analysis. The results of the hot measurement analyses for the DWs A through E area are presented in Table F-10. Barium, lead, manganese, mercury, silver and thorium-232 failed the hot measurement analysis.

Manganese	P (Q)	P	N		COC is at or below background ⁴
Mercury	F (Q)	F	Y	F	COC exceeds background ⁵
Thorium-232	P	P	N		COC is at or below background ⁴

Notes

¹US EPA guidance recommends using the Wilcoxon Rank Sum test (WRS test) and the Quantile test to perform the background comparisons. These tests are outlined in *Statistical Method for Evaluating the Attainment of Cleanup Standards*, Vol. 3 (US EPA, 1994). The WRS test is used to determine whether the removal action has uniformly attained the cleanup goal for a particular constituent of concern (COC) throughout the cleanup unit, whereas the Quantile test is more appropriate to detect when removal action has failed in only a few areas within the cleanup unit.

²The COC passed the statistical test if “P” is indicated. The COC failed the test if “F” is indicated. A “P” or “F” with “(Q)” indicates the pass or fail was qualified due to a limited number of background or confirmation samples, or a limited number of samples above the detection limit.

³All of the DOE Box confirmation samples were collected greater than four feet below ground surface. Therefore, the confirmation data sets were compared with background data collected greater than four feet below ground surface.

⁴This COC is present on site at or below background concentrations. If a COC is detected at or below background levels, it is assumed that it does not contribute to excess or incremental risk and is therefore removed from the risk analysis for the DOE Box area.

⁵Mercury was detected above background and was therefore included in the DOE Box area risk analyses.

Notes

⁽¹⁾ Chemical PRGs for residential soil are from US EPA Region 9 PRGs table, dated February, 2003. Radionuclide PRGs for residential soil are from Radionuclide Toxicity and PRGs for Superfund, dated April 14, 2003 (US EPA, http://epa-prgs.orr1.gov/radionuclides/download/rad_master_prg_table.xls).

Abbreviations

- 95% UCL 95% upper confidence limit on the mean concentration
- Carc. Carcinogenic
- COC Constituent of Concern
- ft feet
- mg/kg milligrams per kilogram
- n/a not applicable
- pCi/g picoCuries per gram
- PRG Preliminary remediation goal concentration [California specific PRG in brackets]
- RBAS Risk-based action standard determined specifically for the LEHR site
- RME Reasonable maximum exposure concentration, the 95% UCL was used as the RME. If less than ten samples were below the detection limit, the maximum detected concentration was used as the RME.

Table F-5. Risk Screening Analysis for Constituents of Concern, DOE Box Area (continued)

Note 1 Since the RBAS for this COC was less than the background value, per the Work Plan, a background comparison was conducted. The sample data set was not above the background data set. Therefore, the COC was not considered a contributor to excess risk from the site, and a RME/RBAS ratio was not calculated for inclusion in the cumulative summation. The COC was removed from further risk screening.

RBAS	Risk-based action standard determined specifically for the LEHR site
RME	Reasonable maximum exposure concentration, the 95% UCL was used as the RME. If less than ten samples were below the detection limit, the maximum detected concentration was used as the RME.

Table F-7. Risk Screening Summary, Reasonable Maximum Exposure/Risk-Based Standard Sums for Removal Action Constituents of Concern from the DOE Box Closure Sampling

Excess Risk	Carc. Scen. 1 RME/RBAS Ratio	Carc. Scen. 2 RME/RBAS Ratio	Carc. Scen. 3 RME/RBAS Ratio	Non-Carc. Scen. 1 RME/RBAS Ratio	Non-Carc. Scen. 2 RME/RBAS Ratio	Non-Carc. Scen. 3 RME/RBAS Ratio
10 ⁻⁶	0.60	1.03	0.00	N/A	N/A	N/A
10 ⁻⁵	0.06	0.103	0.000	N/A	N/A	N/A
10 ⁻⁴	0.006	0.01	0.000	N/A	N/A	N/A
HQ =1	N/A	N/A	N/A	0.00	4.30	0.04

Non-Carcinogenic Scenario 2 Contributors to 4.3 total RME/RBAS ratio	RME/RBAS
Mercury	3.95
Chromium	0.16
Hexavalent chromium	0.15
Remaining risk COCs	0.04

Notes

RME = Reasonable Maximum Exposure = 95% UCL or maximum value (if a 95% UCL was not available)

Abbreviations

Carc. carcinogenic
 COC constituent of concern
 HQ hazard quotient
 N/A not available
 RBAS risk-based action standard
 Scen. scenario
 UCL upper confidence limit

Table F-8. Risk Screening Summary, Reasonable Maximum Exposure/Risk-Based Standard Sums for the Dry Wells A through E

Excess Risk	Carc. Scen. 1 RME/RBAS Ratio	Carc. Scen. 2 RME/RBAS Ratio	Carc. Scen. 3 RME/RBAS Ratio	Non-Carc. Scen. 1 RME/RBAS Ratio	Non-Carc. Scen. 2 RME/RBAS Ratio	Non-Carc. Scen. 3 RME/RBAS Ratio
10-6	3.50	70.85	0.00	N/A	N/A	N/A
10-5	0.35	7.08	0.00	N/A	N/A	N/A
10-4	0.04	0.71	0.00	N/A	N/A	N/A
HQ=1	N/A	N/A	N/A	0.01	10.42	0.13
Carcinogenic Scenario 2 Contributors to 70.85 total RME/RBAS ratio						RME/RBAS
Lead ¹						68.18
Benzene						0.87
Remaining risk COCs						1.8
Non-Carcinogenic Scenario 2 Contributors to 10.42 total RME/RBAS ratio						RME/RBAS
Mercury						3.64
Silver						3.61
Copper						1.71
Cadmium						1.05
Remaining risk COCs						0.41

Notes

¹A histogram comparison shows that lead is only slightly above background (Figure 3).
 RME = Reasonable Maximum Exposure = 95% UCL or maximum value (if a 95% UCL was not available)

Abbreviations

Carc. carcinogenic
 COC constituent of concern
 HQ hazard quotient
 N/A not available
 RBAS risk-based action standard
 Scen. scenario
 UCL upper confidence limit

Table F-9. Hot Measurement Analysis for the DOE Box Closure Sampling

Constituent	Units	Maximum Concentration	Sample ID of Maximum Concentration	Background Concentration (> 4 ft bgs)	Lowest Carcinogenic 10 ⁻⁵ RBAS	Lowest Non-Carcinogenic RBAS

Notes:

¹Established background value for naturally occurring analytes in soil located at depths from 0 to 4 feet below ground surface/ below 4 feet below ground surface. Detection limit used for pesticides, VOCs and SVOCs (*in italics*).

²Results are considered significant enough to require further screening if maximum concentration is greater than 1.5 times background and more than 5% of the data are above background.

³Limit Kd is 1,000 ml/g for inorganic compounds and 10 ml/g for organic compounds.

⁴The first pass or fail is the WRS test result from the comparison for 0 to 4 feet below ground surface. The second pass or fail is the WRS test result from the comparison for greater than 4 feet below ground surface.

⁵Insufficient data were available to demonstrate allowable decision error in WRS test results.

Abbreviations:

Notes:

¹Established background value for naturally occurring analytes in soil located at depths from 0 to 4 feet below ground surface/ below 4 feet below ground surface. Detection limit used for pesticides, VOCs and SVOCs (*italics*).

²Results are considered significant enough to require further screening if maximum concentration is greater than 1.5 times background and more than 5% of the data are above background.

³Limit Kd is 1,000 ml/g for inorganic compounds and 10 ml/g for organic compounds.

⁴The first pass or fail is the WRS test result from the comparison for 0 to 4 feet below ground surface. The second pass or fail is the WRS test result from the comparison for greater than 4 feet below ground surface.

⁵Insufficient data were available to demonstrate allowable decision error in WRS test results.

Abbreviations:

COC constituent of concern
 DL designated-level
 Kd partitioning coefficient
 mg/kg milligrams per kilogram
 ml/g milligrams per gram
 NA not applicable
 pCi/g picoCuries per gram
 SVOCs semivolatile organic compounds
 ug/kg micrograms per kilogram
 VOCs volatile organic compounds
 WRS Wilcoxon Rank Sum

APPENDIX I

MAXIMUM CONCENTRATION OF THE CONSTITUENTS OF CONCERN DETECTED ABOVE BACKGROUND IN THE WASTE CHARACTERIZATION DATA FOR EACH AREA

Notes

- ⁽¹⁾ PRG for total chromium
- ⁽²⁾ PRG for chromium III
- ⁽³⁾ PRG for lead (tetraethyl)
- ⁽⁴⁾ PRG for mercuric chloride

Abbreviations

MCL	maximum contaminant level
mg/l	milligrams per liter
mrem/yr	millirem per year
NA	not applicable or not available
NE	not established
PRG	preliminary remediation goal
