Evaluation of Groundwater Constituents and Seasonal Variation at the Riverton, Wyoming, Processing Site

Executive Summary

Historical groundwater monitoring at the Riverton site included collecting samples for a variety of analyses, including general water quality, inorganics, metals, and radionuclides. Evaluations of these constituents were conducted and presented in past documents, which resulted in four constituents of concern (COCs). This paper presents a reevaluation of 47 constituents using screening criteria that included percentage of detections, comparison to background concentrations, comparison to dietary ranges, and comparison to standards or benchmarks. This reevaluation resulted in seven constituents (in addition to the COCs) that were retained after applying the screening criteria and require additional evaluation via risk assessment or additional sampling. These constituents are antimony, boron, bromide, nickel, selenium, strontium, and tin.

Groundwater sampling at the Riverton site has been conducted on a variable schedule ranging from quarterly to annually. Recent sampling has been conducted on a semiannual basis, with one event in June when water levels are typically higher, and one event in the fall when water levels are typically lower. Data from these sampling events were assessed using the nonparametric Wilcoxon Signed-Rank Test to determine if the data vary seasonally. Results of the statistical test indicate that there is some constituent-specific seasonal variation in groundwater, with the highest concentrations typically occurring in samples collected during the June sampling event. Results also show seasonal variation in all constituent concentrations in the surface water, with the highest concentrations occurring in samples collected during the fall sampling. Limited data exist to assess results from the winter, early spring, and late summer portions of the year, and additional sampling in these quarters is recommended to ensure that the highest-concentration times of year are captured in the monitoring approach.

1.0 Purpose

The purpose of this white paper is to (1) evaluate the groundwater constituents that have been measured historically at the Riverton, Wyoming, Site to make recommendations for each constituent for future monitoring; and (2) provide an analysis of the current and historical sampling frequencies conducted at the site, assess seasonal variations in the data, and make recommendations for the timing of future monitoring.

2.0 Groundwater Constituents

2.1 Background

This section reevaluates 47 constituents that have been monitored since 1985 at the Riverton site to determine if they should be included in the long-term monitoring program. These constituents were initially evaluated in the *Baseline Risk Assessment of Ground Water Contamination at the Uranium Mill Tailings Site near Riverton, Wyoming* (BLRA) (DOE 1995), in which the list was screened to eliminate constituents based on comparison to background, toxicity, and dietary

ranges. This evaluation resulted in a list of 10 constituents of potential concern. These constituents were further evaluated in the *Environmental Assessment of Ground Water Compliance at the Riverton, Wyoming, Uranium Mill Tailings Site* (EA) (DOE 1998a), in which they were screened on the basis of detection limits, comparison to maximum concentration limits (MCLs) established in Title 40 *Code of Federal Regulations* Part 192, and risk. These assessments resulted in the final list of constituents of concern (COCs)—manganese, molybdenum, sulfate, and uranium—which were specified in the EA and identified in the U.S. Nuclear Regulatory Commission (NRC) approved *Final Ground Water Compliance Action Plan for the Riverton, Wyoming, Title I UMTRA Project Site* (DOE 1998b) (GCAP). Although these constituents have been evaluated in the past, and the COCs have regulatory approval, the U.S. Department of Energy (DOE) is committed to reevaluating monitoring programs when site conditions change, as analysis of new data warrants, or as stakeholders express concerns.

At a meeting held in October 2010 among representatives from DOE, the Wind River Environmental Quality Commission (WREQC), the U.S. Environmental Protection Agency (EPA), and the U.S. Geological Survey (USGS), all parties agreed that a new risk assessment should be conducted at the Riverton site. This Supplemental Risk Assessment will be a tool to assess current risks to human health and the environment using the existing, extensive data set compiled over the last 16 years since the BLRA was issued. This assessment will examine potential exposure pathways based on an updated and refined site conceptual model using data from all the impacted media (soil, sediment, biota, vegetation, surface water, and groundwater). The updated study will be a standalone assessment that uses the latest benchmarks, equations, and methodologies. As discussed in the following section, this Supplemental Risk Assessment will be an important tool in the evaluation of constituents at the Riverton site.

2.2 Methodology

Methodology for this evaluation follows the logic and flow chart displayed in Figure 1. This methodology represents a conservative approach for excluding constituents from the long-term monitoring program because the data set uses only data from monitoring wells within the contaminant plumes (monitoring wells where the molybdenum and uranium MCL was exceeded). In addition, this methodology conservatively assumes that the 47 constituents evaluated could be site-related. In a typical assessment, the first step would be to screen out constituents that were not a component of the ore or milling process; however, to be consistent with the list of constituents monitored in the past and with the list of constituents evaluated in the BLRA, all 47 constituents were evaluated. Detailed explanations of each step in the flow chart are provided below.

Step 1: Summary statistics were compiled and are displayed in Table 1. Data summarized in Table 1 and detailed in Appendix A were obtained from DOE's SEEPPro database and will form the basis for discussion in the following Section. Table 1 displays summary data from monitoring wells 0707, 0716, 0718, 0722, 0722R, which are located within contaminant plumes on and downgradient of the former mill site. These wells were chosen because they best represent the site-related plume, and they have a long sampling history for numerous constituents. For example, monitoring well 0707 has been sampled since 1987 for 47 constituents and has had the highest measured concentrations of manganese, molybdenum, and uranium of any well at the Riverton site. Table 1 also displays summary data from background monitoring wells 0710 through 0715. These wells are considered upgradient of the

former mill site based on groundwater elevation data collected over the last 16 years since the BLRA was issued, and they show a consistent groundwater flow direction (DOE 2011).

Step 2: Data were evaluated to determine if a constituent was detected in enough samples to warrant further evaluation. The decision to move on to Step 3 rather than exclude the constituent from long-term monitoring was based on the following criterion. If a constituent was detected in greater than 10 percent of the samples (or undetected in \leq 90 percent of samples), evaluation of the constituent proceeded to Step 3. If this criterion was not met, the constituent was excluded from long-term monitoring.

Step 3: Data were evaluated to determine if a constituent exceeded background. The mean concentration of a constituent in plume monitoring wells was compared to the maximum concentration observed in background monitoring wells. If the maximum background concentration was exceeded, evaluation of the constituent proceeded to Step 4. If this criterion was not met, the constituent was excluded from long-term monitoring.

Step 4: For constituents that are considered to be essential nutrients, data were evaluated to determine if a constituent exceeded a dietary range. The high end of the dietary ranges listed in Appendix A of the *Final Programmatic Environmental Impact Statement of the Uranium Mill Tailings Remedial Action Ground Water Project* (DOE 1996) were used to develop the benchmark (Table 1), which was based on consumption of 2 liters of water per day. If the mean concentration of a constituent in plume monitoring wells exceeded the dietary benchmark, evaluation of the constituent proceeded to Step 5. If this criterion was not met, the constituent was excluded from long-term monitoring.

Step 5: Data were evaluated to determine if a constituent exceeded a standard or risk-based benchmark. If the maximum concentration of a constituent in plume monitoring wells exceeded a standard or benchmark, evaluation of the constituent proceeded to Step 6. If this criterion was not met, the constituent was excluded from long-term monitoring.

Step 6: Data were evaluated against recent data collected by WREQC in June of 2011. The June 2011 sampling event by WREQC is the only recent sampling event in which analyses were conducted for a wide range of constituents. DOE groundwater monitoring in recent years has focused on the regulator-approved COCs, so there is no recent DOE data for most constituents. Constituents that were not screened out in Steps 2 through 5 using DOE data were evaluated through the same steps using WREQC data. If the criteria were met for WREQC data, evaluation of the constituent proceeded to Step 7, and if the criteria were not met, the constituent was excluded from long-term monitoring.

Step 7: Constituents that were not excluded from long-term monitoring in Steps 2 through 6 will be evaluated in the Supplemental Risk Assessment. If the results of the risk assessment indicate the constituent does not pose an unacceptable risk to human health or the environment, then the constituent will be excluded from long-term monitoring, and if the results of the risk assessment indicate an unacceptable risk to human health or the environment, then the constituent will be included for long-term monitoring.

Table 1. Groundwater Constituent Summary

Constituent	Plume Wells ^a				Standard or Benchmark ^{b,d}	Background ^{b,e}

Table 1 (continued). Groundwater Constituent Summary

Constituent	Plume Wells ^a				Standard or Benchmark ^{b,d}	Background ^{b,e}
	Range ^b	Mean ^b	N ^c	Percent Nondetects		
Radium-226	0–2.2	0.35	16	NA	5	0.6
Radium-228	0–12.8	1.92	16	NA	5	2.8
Thorium-230	0–6.82	1.25	16	50	NA	0.7

Color Key

- Greater than or equal to 90 percent nondetects
- Concentrations within dietary range
- Mean concentration of plume wells is less than or equal to maximum concentration in background wells.
- Constituent of concern identified in the EA and listed in the NRC-approved GCAP
- Mean concentration exceeds background concentrations and none of the above applies.

^a Data from surficial aquifer monitoring wells 0707, 0716, 0718, 0722, 0722R; data are from 1987 to 2011.

^b All units are in milligrams per liter for general water quality, inorganic, and metals constituents, and picocuries per liter for radiological constituents. When a constituent was not detected, the detection limit was used for reporting and calculations.

^c Number of observations

^d Standards and benchmarks include Title 40 *Code of Federal Regulations* Part 192, Table 1 to Subpart A; National Secondary Drinking Water Regulations, and the Drinking Water Equivalent Level from EPA's 2011 *Edition of the Drinking Water Standards and Health Advisories*; dietary ranges from the *Final Programmatic Environmental Impact Statement of the Uranium Mill Tailings Remedial Action Ground Water Project*, Appendix A (DOE 1996), high end of the dietary range was used for the benchmark assuming consumption of 2 liters of water per day.

^e Maximum concentration detected from background surficial aquifer monitoring wells 0710, 0711, 0712, 0713, 0714, and 0715; data are from 1985 to 2011. If a constituent was not detected, the method detection limit was used.

^f No standard or benchmark is available, or comparison to a standard was not assessed.

2.3 Constituent Evaluation

This section provides an evaluation of the constituents that should be included in future monitoring; it follows the approach outlined in Figure 1.

Constituents Not Detected (Step 2)

As shown in Table 1, cyanide, nitrite, sulfide, beryllium, chromium, cobalt, mercury, and thallium were not detected in a significant number of samples. These constituents were detected in less than 10 percent of the samples in the plume monitoring wells and, therefore, can be excluded from the long-term monitoring program.

Constituents at Background Levels (Step 3)

Mean concentrations of total organic carbon, ammonia, nitrate as NO₃, phosphate, silica, arsenic, barium, cadmium, copper, iron, lead, silver, vanadium, polonium-210, radium-226, and radium-228 in plume monitoring wells were equal to or less than maximum concentrations in background wells, indicating no groundwater impacts from the former milling activities. Therefore, these constituents can be excluded from the long-term monitoring program. The mean concentration of manganese was also below the maximum background concentration; however, because manganese was identified in the EA as a COC and is listed in NRC-approved GCAP, it will be retained in the long-term monitoring program.

Constituent Evaluation Riverton Processing Site

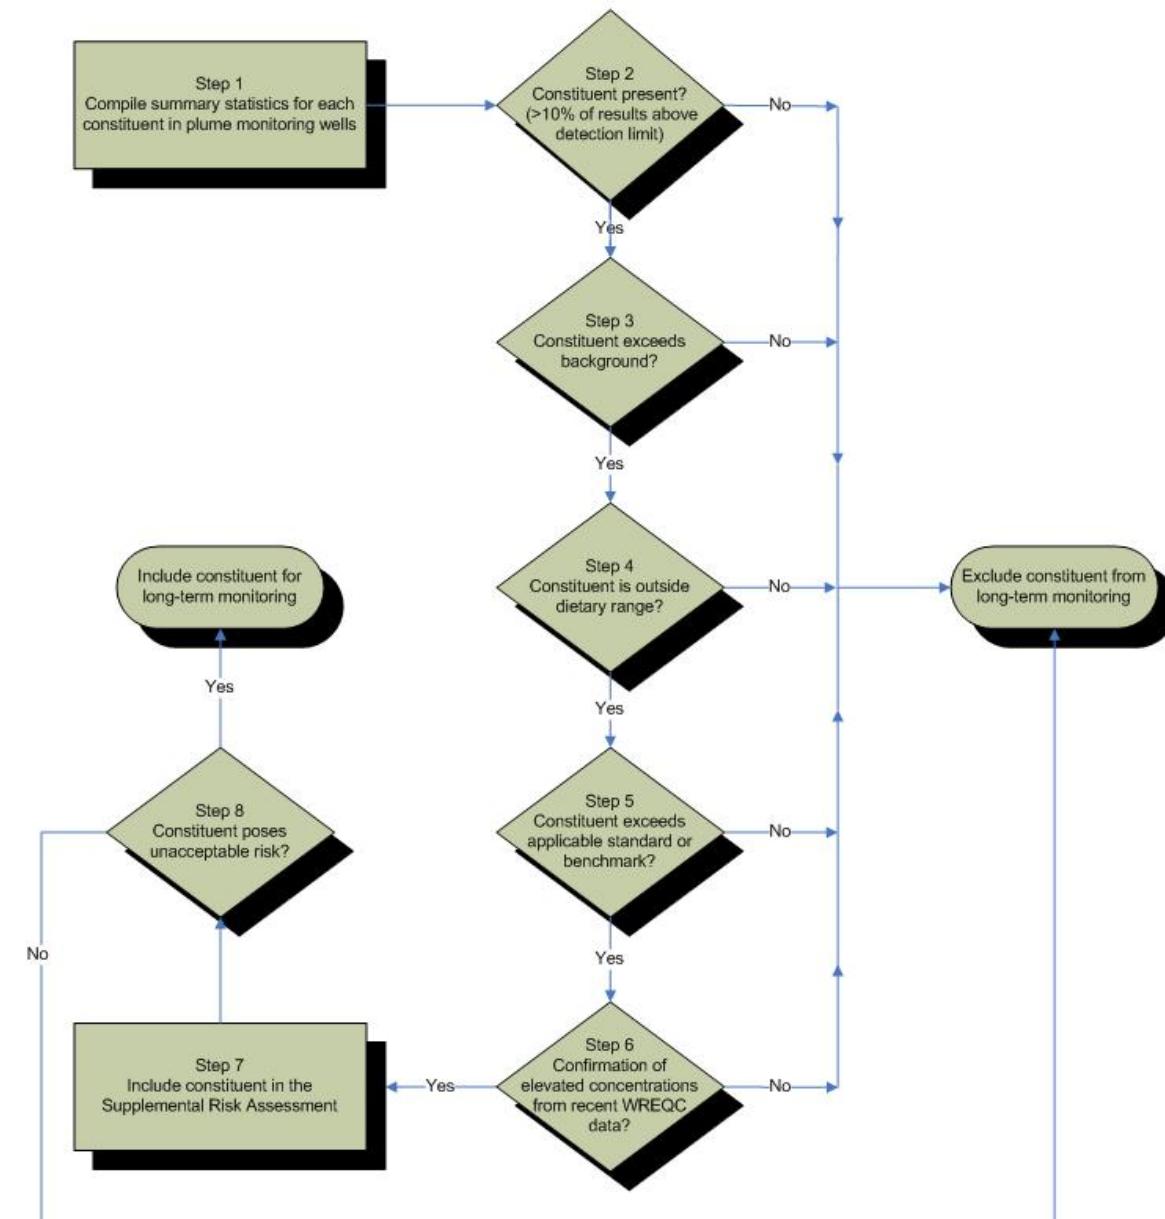

Figure 1. Constituent Evaluation Flowchart

Constituents within Dietary Range (Step 4)

As shown in Table 1, mean concentrations of calcium, chloride, fluoride, potassium, sodium, magnesium, and zinc in plume monitoring wells exceed maximum background concentrations, which indicate impacts to groundwater from the former milling activities. However, mean concentrations of these constituents are within the dietary range for humans and are considered essential nutrients for human health; therefore, these constituents can be excluded from the long-term monitoring program.

Constituents below Standards or Benchmarks (Step 5)

Following the flowchart in Figure 1, the next step is to compare remaining constituents to applicable standards or benchmarks. No constituents were eliminated based on this comparison.

Comparison to Recent WREQC Data (Step 6)

After the screening criteria eliminated the constituents listed above, numerous constituents remain for possible inclusion in the long-term monitoring program. As shown in Figure 1, the next step is to evaluate remaining constituents using recent data that WREQC collected in June 2011 to determine if concentrations are detected and still exceed background. Constituents remaining are evaluated using WREQC data in Table 2.

Table 2. Constituent Evaluation with WREQC 2011 Data

Constituent	2010 WREQC Data Maximum ^a	2010 WREQC Data Background ^{a,b}	Recommendation
Manganese	2.41	<0.01	
Molybdenum	1.3	<0.1	
Sulfate	6,400	385	
Uranium	3.12	0.0105	
Aluminum	<0.1	<0.1	
Lead-210	-1 U	-0.4 U	
Thorium-230	0.1 U	0.006 U	
Bromide		-	
Antimony	Not analyzed	-	
Tin		-	
Boron	0.5	<0.1	Include in Supplemental Risk Assessment
Nickel	0.22	<0.05	
Strontium	6.0	1.0	
Selenium	0.01	<0.001	
Gross alpha	2,140	0.8 U	Met 40 CFR 192 MCL; included in monitoring program
Gross beta	555	3.1 U	Accounted for by monitoring uranium; exclude from long-term monitoring

^a All units are in milligrams per liter except for radiological constituents, which are in picocuries per liter. When a constituent was not detected, the detection limit was used.

^b Concentration from unfiltered sample collected by WREQC in June 2010 from background monitoring well 0710.

Manganese, molybdenum, sulfate, and uranium concentrations exceeded background and applicable standards/benchmarks in samples from recent DOE and WREQC sampling events. These constituents were selected as the COCs for the Riverton site and are specified in the

GCAP, which was approved by NRC; therefore, these constituents will be retained in the long-term monitoring program with no further evaluation necessary.

Bromide, antimony, and tin were not analyzed in the recent WREQC samples; therefore, an evaluation of these constituents is not possible. These constituents would be assessed in the Supplemental Risk Assessment (Step 7) to determine if they pose an unacceptable risk to human health or the environment, and the decision to include them in the long-term monitoring program can be based on the results of the risk assessment.

Results from the WREQC sampling in June 2011 show that boron, nickel, and strontium concentrations continue to exceed background concentrations; therefore, these constituents would be assessed in the Supplemental Risk Assessment, and the decision to include them in the long-term monitoring program can be based on the results of the risk assessment.

Because the selenium concentration in monitoring well 0718 (0.01 mg/L) matched the 40 CFR 192 standard, additional sampling for selenium is warranted until monitoring results indicate that concentrations in all wells in the monitoring network are below the standard.

Results from the recent WREQC sampling indicate that gross alpha and gross beta concentrations in plume monitoring wells remain significantly above background. The elevated concentrations of these gross measurements are a reflection of the presence of radionuclides associated with uranium decay products. For example, the gross alpha concentrations observed are primarily due to the uranium isotopes uranium-234 and uranium-238, and the gross beta concentrations are primarily due to thorium-234 (24-day half-life) and protactinium-234 (1.2-minute half-life), which are intermediate decay products between uranium-238 and uranium-234. Therefore, by continuing to monitor for uranium, these gross measurements are redundant and should not be included in the long-term monitoring program.

2.4 Constituent Summary and Recommendations

Table 3 summarizes recommendations for all constituents based on the evaluation conducted above.

Table 3. Summary of Constituent Evaluation

Constituent	Retain			Reason
	Yes	No	TBD ^a	
Manganese, molybdenum, sulfate, and uranium	X			Specified as COCs in the EA and listed in the NRC-approved GCAP
Antimony, boron, bromide, nickel, strontium, and tin			X	Address in the Supplemental Risk Assessment
Selenium	X			Additional sampling warranted because recent concentration matched the 40 CFR 192 standard in one well.
Gross alpha and gross beta		X		Accounted for by monitoring for uranium
All other constituents		X		Eliminated based on criteria in Figure 1 and data in Table 1

^aTo be determined

3.0 Seasonal Variation

Assessment of seasonal variation in groundwater and surface water data is an important consideration to optimize a long-term monitoring program. Determination of how concentrations of constituents vary seasonally allows scheduling of sampling events during the season (or seasons) of the year when concentrations are highest. Sampling when concentrations are highest will provide a conservative data set when addressing the completion of the natural flushing compliance strategy.

3.1 Background

Groundwater sampling has been conducted on a variable frequency at the Riverton site. Table 4 presents the frequency of monitoring of well 0707, which has the most extensive monitoring history of any well at the Riverton site. During the site characterization phase from 1987 to 1992, sampling was conducted two to four times per year followed by a period of annual sampling through 2003. Monitoring well 0707 was not sampled in 1994 and 1995, although a limited set of wells were sampled during that period. In 2004, sampling frequency was increased from annual sampling to semiannual sampling at the request of WREQC and continues to be conducted on a semiannual basis. In 2005, the semiannual sampling schedule was adjusted to capture a high-flow sampling event in June.

2011						X					X	

Water levels in the surficial aquifer correlate with discharge in the Little Wind River, as illustrated in Figure 2. Flow in the Little Wind River is typically highest in June, which reflects spring runoff conditions from the Wind River Range. Table 5 displays monthly average flow statistics from USGS gaging station 06235500, which is located just downstream of the Riverton site, from 1990 to 2010. As shown in the table, the largest river flows are in June, and flows in the fall, winter, and early spring are low and comparable to each other.

Data from 1988 and 1989 were not used for assessment of seasonal variation because surface remediation of the mill site was occurring at that time, and data would likely reflect various stages of source removal that was in progress rather than true seasonal variation. In addition, data from 1990 to 1992 were not used for assessment of seasonal variation because the limited number of locations sampled did not meet the minimum number of data points required for the statistical test selected, which is described in Section 3.2. Therefore, this assessment of seasonal variation will focus on determining if there is a difference between June and October/November (fall) sampling events using data from 2005 to 2010.

3.2 Statistical Approach

The Wilcoxon Signed-Rank Test (Hollander and Wolfe 1973) statistical test was used for this evaluation. The Wilcoxon Signed-Rank Test requires computing and ranking the differences in paired observations. This statistical test is a nonparametric test and, therefore, does not require a specific distribution of the data (e.g., normal distribution).

The Wilcoxon Signed-Rank Test is used as an alternative to the Paired Student's t Test when determination of a normal distribution of the underlying population cannot be made. The Wilcoxon Signed-Rank Test is used to determine whether there is a difference between paired samples by considering the magnitude of differences. The most widely used application of this test is to determine whether there is a difference between data from before and after an event. The null hypothesis for this test states that there is no difference between the paired samples. The alternative hypothesis states that there is a difference between the paired samples. In this evaluation, this test will be used to determine whether there is a difference between data collected in June versus data collected in the fall, that is, whether there is a statistically significant seasonal difference observed in the constituents.

To compare the June and fall sampling events, five constituents (manganese, molybdenum, specific conductance, sulfate, and uranium) were evaluated in groundwater and surface water for the years 2005 through 2010 (Appendix A). Locations sampled in the June sampling event were matched with the same location sampled in the fall sampling event to create paired samples.

3.3 Groundwater

Table 6 shows the number of paired samples (June/fall) for each groundwater constituent in each year.

Table 6. Number of Paired Groundwater Samples

Constituent	Number of Paired Samples						
	2005	2006	2007	2008	2009	2010	All Years
Manganese	8	9	13	12	13	12	67
Molybdenum	7	9	12	13	13	12	66
Specific Conductance	8	9	13	13	13	12	68
Sulfate	8	9	11	12	13	12	65
Uranium	8	8	13	13	13	12	67

Table 7 shows the results of the statistical test to determine if there is a difference between the paired samples for groundwater between the June and fall sampling events at the 95 percent confidence level. Because the null hypothesis means there is no difference between paired samples, a "yes" answer indicates that there is a statistical difference (seasonal variation) between the June and fall data. Only 5 of the 30 constituent/year combinations (17 percent) show seasonal variation. The analysis for each constituent that considers the data for all the years from 2005 through 2010 indicates that manganese and molybdenum show seasonal variation, while specific conductance, sulfate, and uranium show no significant seasonal variation.

Table 7. Results of the Wilcoxon Signed-Rank Test for Groundwater

Constituent	Is there a difference between paired samples (Yes/No)?						
	2005	2006	2007	2008	2009	2010	All Years
Manganese	Yes	No	Yes	No	No	No	Yes
Molybdenum	No	No	Yes	No	Yes	No	Yes
Specific Conductance	No	No	Yes	No	No	No	No
Sulfate	No	No	No	No	No	No	No
Uranium	No	No	No	No	No	No	No

Table 8 shows which sampling event had the highest average (mean) concentration. As shown in the table, 20 out of 30 constituent/year combinations (67 percent) were higher in June, and for data that considered all years, all average constituent concentrations were higher in June, except for molybdenum.

Table 8. Sampling Event with Highest Average Groundwater Concentration

Constituent	Sampling Event with Highest Average						
	2005	2006	2007	2008	2009	2010	All Years
Manganese	June	June	June	June	Fall	June	June
Molybdenum	Fall	June	Fall	June	Fall	Fall	Fall
Specific Conductance	Fall	June	June	June	June	June	June
Sulfate	June	Fall	Fall	Fall	June	June	June
Uranium	Fall	June	June	June	June	June	June

3.4 Surface Water

Surface water data used for this analysis included results from the oxbow lake, ponds, and Little Wind River locations. Table 9 shows the number of paired samples for each constituent/year combination.

Table 9. Number of Paired Surface Water samples

Constituent	Number of Paired Samples						
	2005	2006	2007	2008	2009	2010	All Years
Manganese	9	No Data	8	9	9	9	44
Molybdenum	9	No Data	9	9	9	9	45
Specific Conductance	9	9	9	9	9	9	54
Sulfate	9	9	8	9	8	9	52
Uranium	9	9	9	8	8	9	52

Table 10 shows the results of the statistical test to determine if there is a statistical difference (seasonal variation) between the paired samples for surface water constituents between the June and fall sampling events at the 5 percent level of significance. As shown in Table 10, seasonal variation is evident in surface water concentrations for all constituents, as 19 of the 28 constituent/year combinations (68 percent) show seasonal variation. In addition, the analysis

for each constituent that considers the data for all the years from 2005 through 2010 indicates that all of the constituents show seasonal variation.

Table 10. Results of the Wilcoxon Signed-Rank Test for Surface Water

Constituent	Is there a difference between paired samples (Yes/No)?						
	2005	2006	2007	2008	2009	2010	All Years
Manganese	Yes	No Data	Yes	No	No	Yes	Yes
Molybdenum	Yes	No Data	Yes	Yes	No	Yes	Yes
Specific Conductance	Yes	Yes	No	Yes	No	Yes	Yes
Sulfate	No	Yes	No	Yes	No	No	Yes
Uranium	Yes	Yes	Yes	Yes	Yes	Yes	Yes

Seasonal variation in the surface water is not unexpected, as concentrations of constituents in the oxbow lake are diluted during June run-off as water from the Little Wind River typically flows into or through the oxbow lake. In the fall, the oxbow lake is fed by groundwater discharge and, therefore, reflects concentrations of the contaminated alluvial aquifer. In addition, concentrations of constituents in other surface water features in the monitoring network are concentrated by lower flows and water levels during the fall sampling event.

Table 11 shows which sampling event had the highest average (mean) concentration. As shown in the table, surface water constituent concentrations are higher in the fall, which is a reflection of higher concentrations in the oxbow lake. All 28 constituent/year combinations (100 percent) were higher in the fall, and for data that considered all years, all average constituent concentrations were higher in the fall.

Table 11. Sampling Event with Highest Average Surface Water Concentration

Constituent	Sampling Event with Highest Average						
	2005	2006	2007	2008	2009	2010	All Years
Manganese	Fall	No Data	Fall	Fall	Fall	Fall	Fall
Molybdenum	Fall	No Data	Fall	Fall	Fall	Fall	Fall
Specific Conductance	Fall	Fall	Fall	Fall	Fall	Fall	Fall
Sulfate	Fall	Fall	Fall	Fall	Fall	Fall	Fall
Uranium	Fall	Fall	Fall	Fall	Fall	Fall	Fall

3.5 Sampling Frequency Summary and Recommendations

Statistical analysis indicates a slight constituent-dependent, seasonal variation in the groundwater data between the June and fall sampling events, and groundwater concentrations tend to be higher in June. For surface water, statistical analysis indicates considerable seasonal variation between the June and fall data, which is attributed to the oxbow lake, and surface water concentrations are generally higher in the fall. These results are summarized in Table 12.

Table 12. Summary of Seasonal Variation

Constituent	Seasonal Variation (Yes/No)	Highest Average
Groundwater		
Manganese	Yes	June
Molybdenum	Yes	Fall
Specific Conductance	No	June
Sulfate	No	June
Uranium	No	June
Surface Water		
Manganese	Yes	Fall
Molybdenum	Yes	Fall
Specific Conductance	Yes	Fall
Sulfate	Yes	Fall
Uranium	Yes	Fall

This evaluation indicates that some seasonal variation exists in the data between the June and fall sampling events; however, the limited data set did not allow evaluation of seasonal variation at other times of the year. To determine if constituent concentrations vary at other times of the year and if constituent concentrations are higher at other times of the year, it is recommended that sampling be conducted during other seasons of the year. The NRC-approved compliance strategy of natural flushing is a long-term strategy with current groundwater modeling predicting approximately 75 years before aquifer restoration is complete; therefore, a high-frequency sampling schedule (e.g., quarterly) is not warranted. For cost-effective sampling in other seasons, it is recommended that the sampling frequency remain semiannual with one sampling event in June (high flow) and rotating the second sampling event to a different season (late summer, winter, and early spring). It is recommended that this sampling schedule be in place until a sampling event has been conducted in each season. This recommended schedule is shown in Table 13.

Table 13. Proposed Sampling Schedule

Year	Month Sampled											
	Jan	Feb	March	April	May	June	July	Aug	Sept	Oct	Nov	Dec
2012						X						X
2013			X			X						
2014						X			X			

Evaluation of the additional seasonal variation will be conducted using analysis of variance (ANOVA). ANOVA is a one-way parametric F-test statistical procedure to determine whether there are statistically significant differences in mean concentrations among a set of groups. Two common applications of ANOVA in environmental cleanup are to test if there is a difference between constituent concentrations in background wells and those in monitoring wells and to determine if there is a difference in data collected before and after remediation. As stated previously for the Wilcoxon Signed-Rank Test, ANOVA will be used to determine whether there is a difference between data collected in June and data collected at other times in the year.

Like the two-sample t-test, the one-way ANOVA is a comparison of population means. However, the one-way ANOVA is a comparison of several populations or groups. For example,

a group of data would consist of uranium data collected in June 2012 or uranium data collected in December 2012. Sampling according to the schedule in Table 13 would result in six groups of data for each of the analytes considered. This test requires a minimum of four data points (locations) within a group to be statistically significant; this minimum number will be exceeded in the planned groundwater (12 wells) and surface water (9 locations) sampling.

The null hypothesis is that all the groups have the same population mean. Computation of the F-statistic is the first step of the ANOVA procedure. It can only determine whether any significant mean difference exists between the possible pairs of data groups, and not whether specific groups differ from one another. When a significant F-test is registered, individual tests between each pair of groups need to be conducted. These individual tests, known as *post-hoc comparison* or *contrasts*, are a specially constructed series of t-tests.

4.0 Conclusions

Historical evaluation of 47 constituents monitored at the Riverton site narrowed the list of constituents of potential concern to the four constituents specified in EA and listed in the GCAP. This reevaluation of constituents using extensive data collected by DOE and recent data collected by WREQC has identified six additional constituents (antimony, boron, bromide, nickel, strontium, and tin) that require additional consideration based on the screening criteria presented in this paper. These constituents can be further evaluated via a Supplemental Risk Assessment to determine if measured concentrations pose an unacceptable risk to human health and the environment. In addition, recent WREQC data indicated that the selenium concentration in one well equaled the 40 CFR 192 groundwater standard; therefore, additional groundwater monitoring for selenium is warranted.

Sampling has been conducted on a variable schedule at the Riverton site. Data have been insufficient to determine seasonal variation in all seasons of the year, as limited data have been collected in the winter, early spring, and late summer seasons. There has, however, been sufficient data to determine differences between the June and fall sampling events.

In general, concentrations of COCs in groundwater show a slight constituent-dependent seasonal variation between June and fall sampling events, and concentrations are typically higher in June. This is likely a result of higher water levels mobilizing more contaminants from the vadose zone into the groundwater. For surface water, there is seasonal variation for all COCs, and contaminant concentrations are higher in the fall because lower water levels and flows in the surface water tend to concentrate contaminants.
