SUBJECT: Contract No. DE-AC24-97OH20044
CERCLA Documents for Parcel 4

REFERENCE: Statement of Work Requirement C 7.1e -- Regulator Reports

Dear Mr. Provencher:

BWXT of Ohio has completed the following CERCLA products for public review in support of the transfer of Parcel 4: Residual Risk Evaluation, Screening Level Ecological Risk Assessment and the Proposed Plan for Parcel 4.

Pending approval from your office to release the documents to the public, copies will be placed in the CERCLA Public Reading Room for a thirty day public review period that starts December 18, 2000 through January 16, 2001. If you or members of your staff have any questions regarding the documents, or if additional support is needed, please contact Dave Rakel at extension 4203.

Sincerely,

Jeffrey S. Stapleton
Manager, Environmental Safeguards & Compliance

Dear Dr. Jeff Fisher and Ms. Cathianne Watkins:

The Core Team, consisting of the U.S. Department of Energy Miamisburg Environmental Management Project (DOE-MEMP), U.S. Environmental Protection Agency (USEPA), and the Ohio Environmental Protection Agency (OEPA), appreciates your comments on the Residual Risk Evaluation for Parcel 4. Attached are our responses.

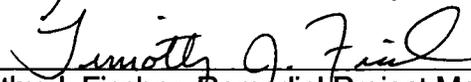

Should the responses to comments require additional detail, please contact Rob Rothman at (937) 865-3823 and we will gladly arrange a meeting or telephone conference.

Sincerely,

DOE/MEMP:

Robert S. Rothman, Remedial Project Manager

**Comments Received on the
Parcel 4 Proposed Plan and Risk Evaluations
from
Dr. Jeff Fisher and Cathianne Watkins
January 2001**

General Findings in Public Review Draft (Rev 0)

Comment 1:

The level of contamination of the soil and groundwater at this parcel require restrictions on the use of this property. For example, constructing basements, using unpaved access roads, driveways and patios are not recommended. The type of industry that locates on the property is an issue. Food service and child care facilities are not recommended. The recommended institutional controls were listed (with no detail) in the document. The authors of the human health risk assessment did not present a specific opinion concerning the site, other than suggesting the risk assessment is 'conservative' and institutional controls will provide adequate protection.

Response :

The Parcel 4 RRE was conducted to evaluate human health risks associated with residual levels of contamination remaining within the area to ensure that future users of the land will not be exposed to contaminant levels that would pose unacceptable risks. The RRE was not intended to be a risk management document. The *Risk Assessment Guidance for Superfund Volume 1 Human Health Evaluation Manual (Part A)*, Section 9.1.1, Page 9-2 recommends avoiding the drawing of "risk management" conclusions within a risk assessment. The risk managers do agree that this parcel requires restrictions therefore the Record of Decision will state : "In order to maintain protection of human health and the environment at Parcel 4 in the future, the institutional controls to be adopted will ensure:

- Maintenance of industrial/commercial land use;
- Prohibition against residential use;
- Prohibition against the use of groundwater;
- Site access for federal and state agencies for the purpose of sampling and monitoring; and
- Prohibition against removal of Parcel 4 soils from the DOE Mound property (as owned in 1998) boundary without approval from the Ohio Department of Health (ODH) and the Ohio Environmental Protection Agency (OEPA)."

Comment 2:

An area of concern is off-site migration of COPCs and other materials that were removed from the risk analysis, but are known human carcinogens.

Contamination of this parcel apparently occurred from soil runoff, resuspension of dust, and atmospheric disposition of stack emissions. This parcel represents, for the most part, the 'unused' portion of Mound, but the soil is contaminated to a degree that one can argue for clean up of soil. If no clean-up of soil occurs, the current and future theoretical health risks to the immediate off-site community need to be included in this document. Discussions (or map) are needed to delineate 1) the distribution pattern of radionuclides and chemicals in the soil, and 2) the modes of transport of these radionuclides from their source to this parcel and the adjacent community since this soil contamination in this parcel is apparently not the result of work activity in this parcel.

Response:

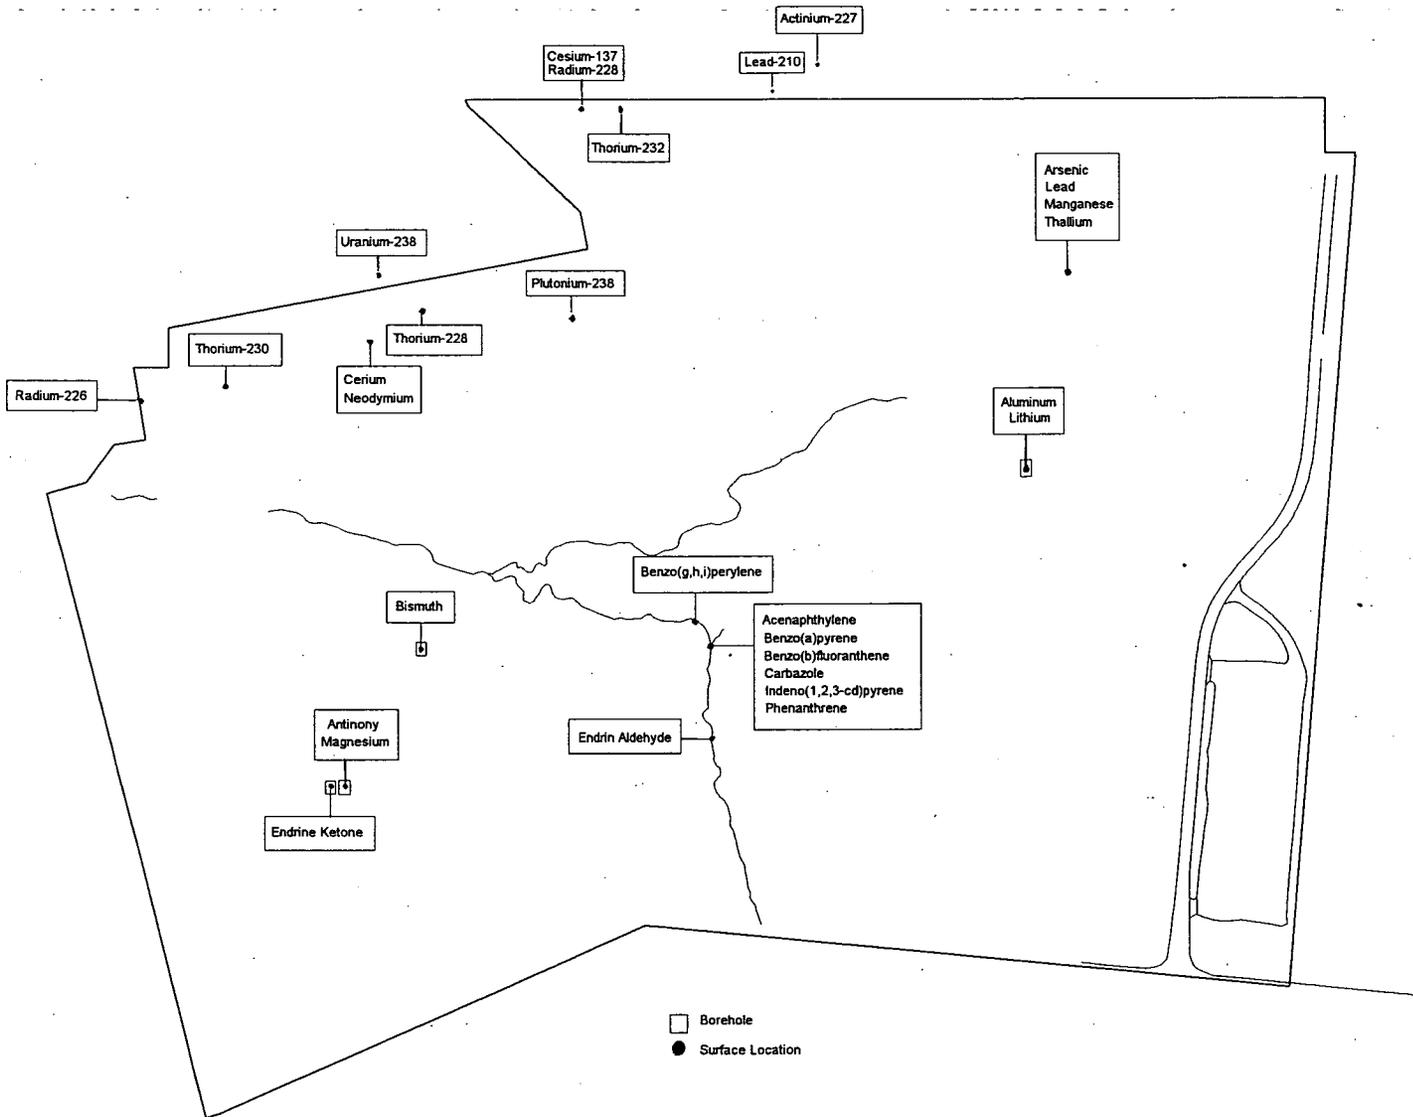

This Residual Risk Evaluation was prepared according to the Residual Risk Evaluation Methodology (RREM). This methodology focuses on the risks within the parcel. According to the Mound 2000 Work Plan, off-site risk will be addressed in the off-site or final Record of Decision and its supporting risk evaluation.

No plant operations, no spills, and no dumping activities are known to have occurred on Parcel 4. The property did receive surface runoff from the adjacent plant operations, which has potentially contaminated Parcel 4. In 1995, a drainage control system was installed along the road north (and uphill) of Parcel 4 to prevent additional surface runoff. Parcel 4 was evaluated using all available sampling data. All carcinogenic and non-carcinogenic constituents detected in Parcel 4 were evaluated in the RRE unless they screened out using the RREM screening techniques. Although the RRE does evaluate indirect exposure to contaminants that may migrate through air or groundwater, it does not evaluate off-site exposure. The purpose of the RRE is to ensure that future on-site users of the land will not be exposed to contaminant levels that pose unacceptable risks following a transfer of ownership. The evaluation of off-site risks is not covered by the RREM. Further speculation as to how contaminants came to be located in Parcel 4 media would not improve the accuracy of the RRE.

A map will be added to the Final version of the Parcel 4 RRE that shows the location of the soil COPCs maximum concentration.

Comment 3:

The community that surrounds this site deserves attention and should not be overlooked. What can Mound say to the public about health and safety for individuals that live adjacent to the site if no remedial action (clean-up) is taken? What can Mound say to the public about working on this parcel if institutional controls are instituted? Kids, pregnant women, and young adults will visit this site! What type of activity (historical or current) at the Mound is responsible for the hand-full chemicals and radionuclides that are driving this parcel risk assessment?

Locations Of Maximum Observed Value For COPCs That Did Not Screen Out of Parcel 4 RRE

Response:

The community that surrounds the Mound facility should be protected, however the evaluation of off-site risks is not covered by the RRE. The purpose of the RRE is to assess potential health risks associated with residual levels of contamination remaining within a parcel prior to its release for future use. The future use scenarios specified by the RRE (i.e. construction worker, site employee) assume that adult workers will be chronically exposed to residual contamination in soil, groundwater, and air. Since the RRE used reasonable maximum exposure (RME) assumptions, actual risk levels for site employees and construction workers are not likely to exceed the levels presented in the RRE. Furthermore, the use of institutional controls limiting exposures to soil and groundwater are planned to ensure that on-site conditions are protective of future receptors.

Given the projected industrial/commercial future use for the site, it is unlikely that children and pregnant visitors would be chronically exposed to on-site contaminants. If exposures to children and pregnant visitors were to occur, those exposures are expected to be brief in duration and below any incremental cancer or adverse effect levels as modeled by the construction worker and site employee scenarios within the Parcel 4 Residual Risk Evaluation. Much lower for instance than a construction worker who was assumed to be exposed through incidental ingestion of soil, dermal contact with soil external radiation exposure, inhalation of airborne dust and vapors, ground water ingestion, dermal contact with ground water and inhalation of vapors released by ground water while showering. If on-site conditions are protective of the highly exposed construction worker, it is anticipated that on-site conditions would be protective of occasional site visitors. Pregnant employees are restricted from access to radiological work areas, and currently there are no radiological work areas in Parcel 4. Radiation levels on Parcel 4 are well below levels that would require workplace restrictions for pregnant women. The restrictions on development and use of the property (some of which specifically prohibit "children under eighteen years of age") are listed in detail in the Quit Claim Deed which is Appendix A of this Record of Decision.

Current and future risk due to antimony in groundwater was estimated using the maximum concentration detected. For chromium, it was assumed that all chromium detected was present in the most toxic, hexavalent state. Hexavalent chromium is not naturally occurring and requires strong oxidizing conditions to persist. Assuming that contaminants are present at the maximum concentration detected and assuming that contaminants are present only in their most toxic form is likely to result in an overestimation of actual risk levels.

Although the focus of this evaluation is Parcel 4, the offsite population has not been forgotten. Mound's effluent monitoring and environmental surveillance continues, is reported to the public via the Annual Site Environmental Monitoring Report and other means, and will continue until the end of the Exit

Project. The effluent monitoring program focuses on releases from the site, i.e., stack and wastewater discharges. The environmental surveillance program involves sample collection and analysis of ambient air, regional water supplies, sediments, onsite and offsite groundwater, and foodstuffs.

Screening Level Ecological Risk Assessment Parcel 4

Comment 4:

The ecological risk assessment was easier to read, generally. Did Mound formally sample for the two species, the Indiana bat and the eastern massasauga rattlesnake? If not, why? Succinct statements needs to be included about the strength of the data concerning a census of what does live on this site. If historical data is available, are there any trends? How will future use of the site effect the current population of wildlife? Development of the site means removal of several species. What are the species that will be affected by development? Are wildlife contaminated with chemicals or radionuclides, from this site, that is, is there any data on the measurement of these materials in carcasses?

Response:

No formal sampling for the Indiana bat and the eastern massasauga was conducted. The habitat required by the Indiana bat was not found to be present and no eastern massasauga specimens were collected during the comprehensive 1992-1993 OU9 Ecological Characterization study. Careful examination of all habitats on Parcel 4 in March 2000 revealed minor changes in certain habitat categories related to succession of the plant communities. However, no significant physical changes have occurred since completion of the Operable Unit 9, Ecological Characterization study. For this reason, it is assumed that the Indiana bat and the eastern massasauga do not occur on or in the vicinity of Parcel 4.

Evaluating trends in species populations, impacts of development on wildlife, and tissue analysis are beyond the scope of a Screening Level Ecological Risk Assessment (SLERA) for a variety of reasons. First, a SLERA focuses on the potential for adverse effects on wildlife from chemical stressors, not physical or biological stressors. Second, impacts of future developmental actions have been addressed in the Environmental Assessment: Disposition of Mound Plant's South Property (DOE/EA-1239 June 1999). Third, community analysis and tissue bioassays are typically performed in a baseline Ecological Risk Assessment, using the results of the SLERA to focus quantitative field studies on those contaminants that pose a potential for adverse effects on specific wildlife species.

Comment 6:

Screening potential constituents of potential concern for surface soil samples less than 2 inches in depth only invalidates this pathway. This surface soil exposure issues for wildlife that do not live in soil is the same issue with humans. Granted, the expected disturbance of soil and potential exposure is expected to be with the surface layer of soil, but for this site, with industrial development and a construction worker scenario, removal or relocation of soil is expected. When this occurs, deep soil is brought to the surface and is a potential source for surface soil exposure. Re-accomplish the ecological analysis using 'deep' surface soil.

Response:

Samples collected within the 0 – to 2 -feet depth below ground surface were evaluated in the SLERA.

Specific Findings

Comment 1:

The ecological and human health documents are incorrect when referring to hazard index values as 'risk' projections. Only the cancer calculations are risk projections based on a slope or dose-response. There are no dose-response analyses for non-cancer human health effects or the ecological effects using a LOAEL or NOAEL approach with uncertainty factors. Please correct this technical deficiency in the documents. Nothing can be inferred in terms of risk from a HI value greater than 1.0 (other than segregating chemicals or radionuclides in terms of mode of action). So, a HI value of 1.1, 10 or 100 is very deceptive to interpret, unless the toxicology data and uncertainty factors used to derive a toxicity factor are evaluated. Bench mark dose response values are needed for noncancer 'risk' projections.

Response:

We agree that hazard index values are not "risk" projections. However, the text improvements requested will not impact the remedy selected for this parcel. These improvements will be applied to the next parcel. We also agree that the interpretation of HI values greater than 1 is complex and deceptive to interpret (see RAGS Part A, Section 8.2.2, page 8-14). Segregation of hazard indices requires identification of the major effects of each chemical, including those seen at higher doses than the critical effect (e.g. the chemical may cause liver damage at a dose of 100 mg/kg-day and neurotoxicity at a dose of 250 mg/kg-day). Major effect categories include neurotoxicity, developmental toxicity, reproductive toxicity, immunotoxicity, and adverse effects by target organ. Although higher exposure levels may be required to produce adverse health effects other than the critical effect, the reference dose can be used as the toxicity value for each effect category as a conservative and simplifying step. If

the segregation is not carefully done, an underestimation of true hazard could result.

Comment 2:

Add an appendix to the Residual Risk Evaluation Parcel 4 document with the statistically derived background concentrations (mean, range, n, and standard deviation) for chemicals and radionuclides.

Response:

The background values used in the Parcel 4 RRE were taken from the Mound 2000 RREM Appendix A. The soil background values were established in the *Operable Unit 9 Background Soils Investigation Soil Chemistry Report* (September 1994). The groundwater background values were established in the *Operable Unit 9 Hydrogeologic Investigation Groundwater Sweeps Report* (April 1995). Since the background values were not recalculated and were published along with the RREM, these values will not be repeated in this RRE. Mound stakeholders were provided with an opportunity to critically evaluate the background values when the public review draft of the RREM was issued. A citation referring the reader to Appendix A of the RREM will be added to the Parcel 4 RRE.

Comment 3:

The updated RBGV calculations were very helpful. This presents a systemic problem for future risk assessments because citation of prior outdated risk guidance documents is not appropriate. Please create a RBGV document for the public that is current for the two worker scenarios and can be cited in future risk assessments.

Response:

Thank you for the positive feed back. We are aware of the challenge of maintaining up-to-date values for the site. There are a few options in discussion – one is the approach you have suggested.

Comment 4:

SOIL: Table 5.19, total residual risk for parcel 4, summary table, (no page number) of the Residual Risk Evaluation Parcel 4 document. This sums it up! Technically, combining the cancer calculations for chemicals and radionuclides makes no sense. Combining rads and chemicals make sense only if the mechanism of action of the chemical is thought to be genotoxic by production of hydroxy radicals or direct alkylation of DNA. However, given the lumping of these data, the theoretical excess cancer risks are 1.0 in 10,000 from exposure to contaminated soil for the site employee and 3.3 in 100,000 for construction worker for parcel 4. Future use of water as a drinking source presents

unacceptable risks. However, there are drinking water standards in place (ARARs) to set acceptable standards, both on site and off site. This is not true for soil. The calculations in this document will be used to determine the acceptability of the soil in parcel 4.

Is the USEPA and OEPA using total residual risk or incremental risk (total residual risk- background risk)? The reality is that parcel 4 imposes excess theoretical cancer risks above background and is borderline in terms of acceptability as it stands. If only total residual risk is required, then remove the incremental risk calculations. These calculations do not add information to the document. If incremental risk is used to establish soil safety criteria, then a public review of the adequacy of the background levels is needed. I do not believe that the public critically evaluated these data. The set point of $1e-4$ to $1e-6$ for excess cancer risks is misinterpreted or ill defined in the document. The site is the entire Mound facility (and the off-site locations which is another issue).

If the theoretical cancer risks for soil at parcel 4 are at $6.5e-5$ for incremental risk or $1.1e-4$ for total residual risk, then what is the probability that the entire Mound facility will meet the criterion of $1e-4$ to $1e-6$, given that this is the 'cleanest' portion of the site? A near zero probability is probably the answer. Antimony in water and low level radionuclides in soil are driving the health concerns. Can 'hot spot' removal of soil help in reducing the calculated health risks for soil at parcel 4 and can treatment of water for the site be considered? Is the current thinking to write-off the water supply and not deal with it as eluded to in the institutional controls?

Response:

The commentor makes a good point, technically the summation of cancer calculations for chemical and radionuclides is conservative. Cancer slope factors are defined differently for radionuclide and non-radionuclides. The document *Radiation Risk Assessment at CERCLA Sites: Q&A* (EPA540/R199/006, December, 1999) states:

"Excess cancer risk from both radionuclides and chemical carcinogens should be summed to provide an estimate of the combined risk presented by all carcinogenic contaminants as specified in OSWER directive 9200.4-18 (1997). An exception would be cases in which a person reasonably can not be exposed to both chemical and radiological carcinogens...

In the absence of additional information, it is reasonable to assume that excess cancer risks are additive for purposes of evaluating the total incremental cancer risk associated with a contaminated site."

These risks were summed to allow risk management decisions to be made on cumulative effects that might be missed if the risks were evaluated individually. The presentation of total, background, and incremental risk follows the RREM.

Risk management decisions focus on site related risks which are represented in the incremental sections. Carcinogenic risk results were compared to the acceptable risk range of 10^{-4} to 10^{-6} (increase in cancer risk of one human in ten thousand to one human in one million) as specified by the National Contingency Plan.

Comment 5:

Provide a list of authors and their affiliations on the 1st page of the documents.

Response:

The number of contributors to these reports is large; the number of organizations participating in the development of these documents is large. Because of this and the fact that the documents represent the positions of US EPA, DOE, and OEPA concerning the site, we have chosen not to provide a list of authors and affiliations.

The Mound Core Team
P.O. Box 66
Miamisburg, Ohio 45343-0066

Mr. Peter Townsend
Hydro-Log
PO Box 555
Yellow Springs, Ohio 45387

Dear Mr. Townsend:

The Core Team, consisting of the U.S. Department of Energy Miamisburg Environmental Management Project (DOE-MEMP), U.S. Environmental Protection Agency (USEPA), and the Ohio Environmental Protection Agency (OEPA), appreciates your comments on the Proposed Plan for Parcel 4. Attached are our responses.

Should the responses to comments require additional detail, please contact Rob Rothman at (937) 865-3823 and we will gladly arrange a meeting or telephone conference.

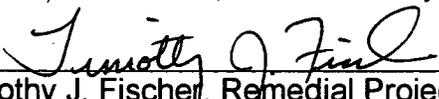

Sincerely,

DOE/MEMP:

Robert S. Rothman, Remedial Project Manager

USEPA

Timothy J. Fischer, Remedial Project Manager

Brian K. Nickel, Project Manager

**Comments Received on the
Parcel 4 Proposed Plan and Risk Evaluations
from
Peter Townsend
January 2001**

The Proposed Plan for Parcel 4 contains three areas of concern. These are: 1) groundwater protection and groundwater monitoring in the Buried Valley Aquifer (BVA) downflow from Parcel 4 is not considered, 2) the source of groundwater contaminants is not considered, and 3) the source of groundwater contaminants is most likely airborne fallout from Mound Lab emissions. This study implies that other off-site areas, particularly to the east, west, and north of Mound Labs would have considerable heavy metal and radionuclide fallout, and should receive similar groundwater investigations.

Concerns:

- 1) The Proposed Plan for Parcel 4 protects future groundwater use within Parcel 4 through deed restrictions, which will prevent future Parcel 4 landowners from installing wells. The groundwater flow regime for Parcel 4 is shown on a map on page 8 in Appendix B of the *Residual Risk Evaluation, Parcel 4*. The groundwater flow map is presented on page 2 of these comments. This map shows that the groundwater flow from Parcel 4 descends from the east and northern boundaries, and enters the Buried Valley Aquifer (BVA). In the BVA are the groundwater supply wells for the Mound Laboratory, also downflow from Parcel 4. The Hazard Index (HI) for groundwater within Parcel 4 is above 1, and has resulted in the decision to impose deed restrictions, eliminating future land owners from installing wells on their property. There should be a discussion in the Proposed Plan for Parcel 4 about the impact of the groundwater flow from parcel 4 into the BVA, and the possible impact on the Mound Water Supply Wells. Also, there should be provisions for monitoring groundwater descending from Parcel 4 into the BVA, to look for possible migration of contaminated groundwater from Parcel 4 into the BVA and the Mound Water Supply Wells.

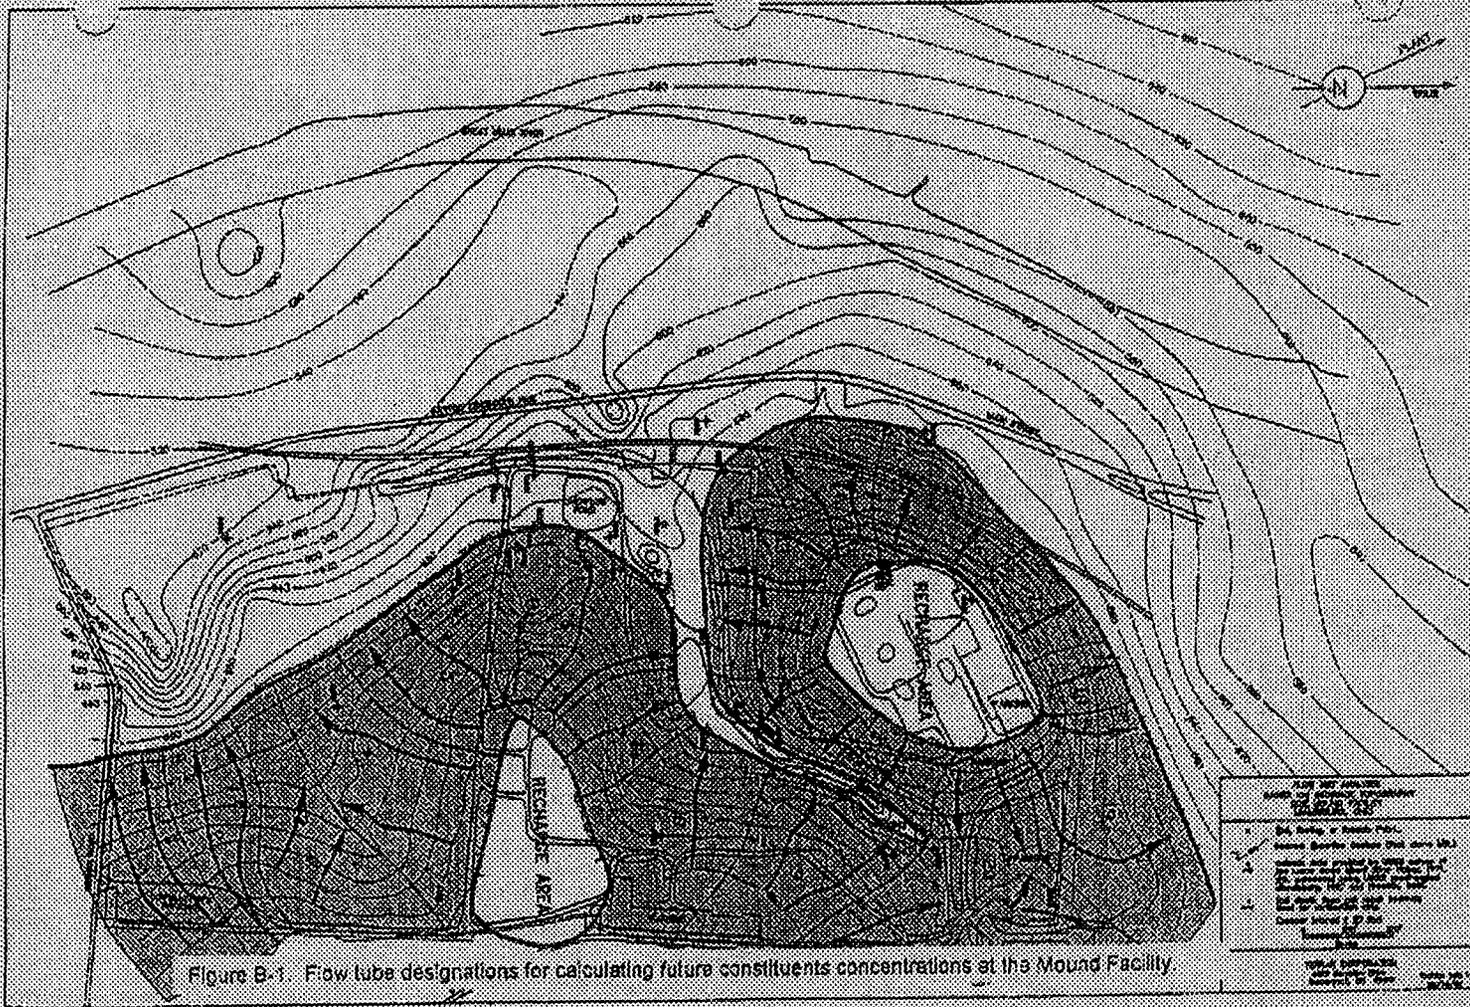

Response:

There may be some misinterpretation of the Parcel 4 RRE results. The groundwater data are not solely from Parcel 4. Groundwater quality data from wells across the site; i.e, located on and near (including the Mound Plant process areas) Parcel 4 were used to calculate the current and future potential impact of measured chemicals of concern (COCs) at the closest existing groundwater receptor, the Mound water supply wells (see

Appendix B of the RRE). As discussed in the Parcel 4 RRE, the calculated unacceptable HI for the current groundwater scenario is driven largely by the result of a few suspect antimony concentrations measured nearly a decade ago in the production wells. The future groundwater scenario is driven largely by total chromium, assumed to be hexavalent chromium. There is no indication that groundwater COC concentrations beneath Parcel 4 have significantly contributed to the elevated HI.

There is an additional source of uncertainty surrounding the groundwater measurements used in the RRE. The sampling method itself is believed to produce turbid samples which would yield results for measurements of metals that are not representative of the groundwater. Such results would be biased high. (*1999 Comparative Well Study*, unpublished) The new micro purge, low flow sampling is being implemented for the groundwater sampling network. The micro purge, low flow sampling will provide more consistency and reduce the uncertainty. We will share the results of this effort as they become available.

Also, Mound's environmental surveillance program will continue after Parcel 4 is transferred. The on-site groundwater monitoring program will continue. The Operable Unit One groundwater treatment and its monitoring will continue. The production wells will be monitored for Safe Drinking Water Act compliance until the site transitions to city water. In addition, monitoring as a part of Post Closure Stewardship will be developed in detail prior to the final parcel transfer.

- 2) Parcel 4 was a farm purchased by Mound Laboratories in 1981. The public has been informed that Parcel 4 was never used by Mound Labs to store or handle any chemicals, wastes, or metals. However, groundwater tests reported in the *Residual Risk Evaluation, Parcel 4* document show that a large number of heavy metals and radionuclides occur in the groundwater at Parcel 4. Metals found in groundwater at Parcel 4 are shown on the attached page. This page is Table 2.9 from the *Residual Risk Evaluation, Parcel 4*.

Table 2.9 shows a number of metals present, in many samples, that would not normally occur in such high amounts. For example, chromium was detected in 78 of 120 tests at concentrations up to 7,400 times higher than expected background concentration; copper was detected in 81 of 117 tests at concentrations up to 430 times higher than expected background concentration; and nickel was detected in 82 of 120 tests at concentrations up to 330 times higher than expected background concentration. Table 2.8 in the *Residual Risk Evaluation, Parcel 4* document, page 5, shows radionuclides present in a number of samples at levels several times higher than expected background values.

An interesting and important question is where did these metals and radionuclides come from? How did they get in the groundwater at this site? These are not materials that would come from farming or other land use from before Mound purchased the property. If Mound never used this property, then how did these contaminants arrive? Most of this property is not downhill from Mound, so these materials could not have washed off the Mound. The only reasonable mode of arrival is from airborne fallout.

Figure 1 of these comments, shown on page 6, is a contour map of average annual air concentration of Pu^{238} for 1997. Figure 1 is contoured in increments of 1×10^{-18} uCi/mL from 1 to 10, and above 10, contours are omitted and raw data values are presented because air concentrations at Mound are so high that contours near the lab would be too close together.

Figure 1 shows that Pu^{238} air concentrations drop off rapidly away from the Mound Laboratory, but note on Figure 1 that Parcel 4, located in the southern 1/3 of the Mound Property, receives considerable Pu^{238} fallout as indicated by this contour map. Note also that the Pu^{238} contaminant plume extends beyond the Mound Plant in all directions, but most notably to the north and west, into areas of Miamisburg that adjoin Mound facility. Figure 1 strongly shows off-site airborne emissions of Pu^{238} .

Figure 2 shows the number of air monitoring stations in place from 1992 to 1998. Table 1 lists air monitoring station numbers and gives data values for 1996 and 1997 Pu^{238} levels at each station.

UCL = Upper Confidence Limit

EPC = minimum of 95% UCL or maximum detected concentration

NO < Background Value

NC = 95% UCL not calculated, less than 20 samples in the data set.

Figure 1. 1997 average Plutonium 238 concentration in the air around the Mound Plant ($10E-18\text{uCi}/\text{mL}$)

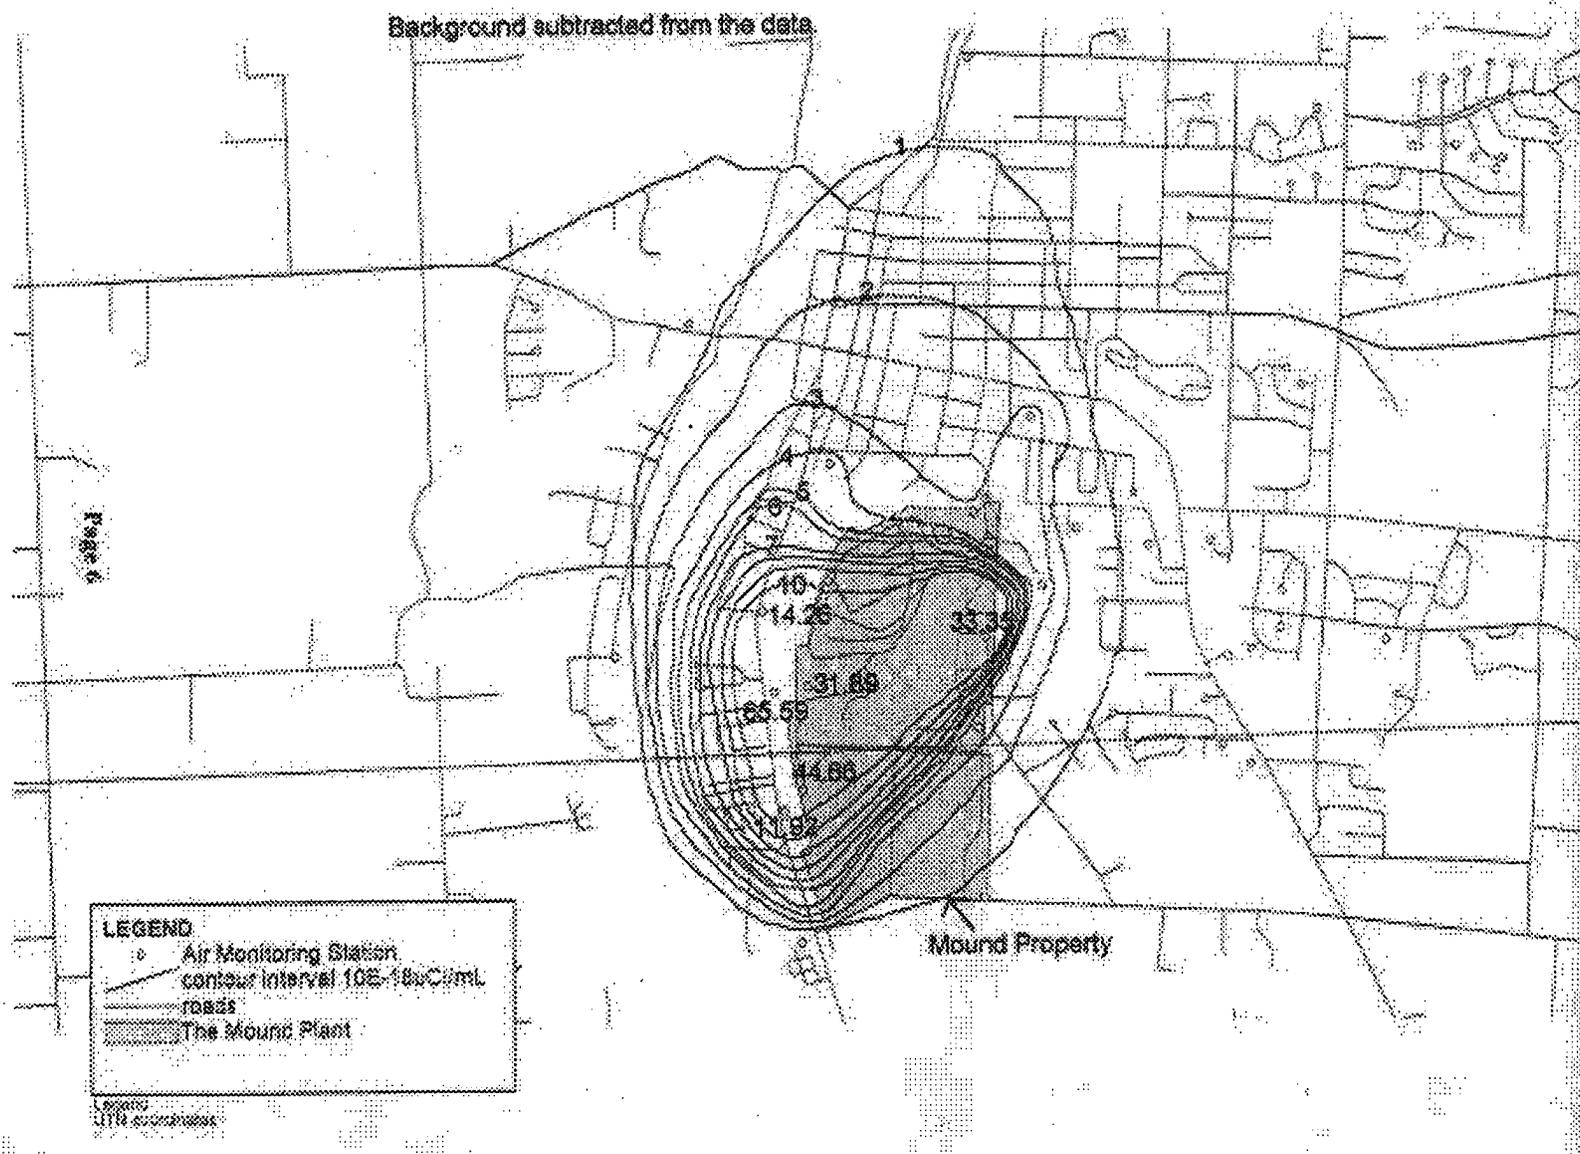

Figure 3 of these comments is a contour map of average annual air concentration of Pu²³⁸ for 1996. Figure 3 is contoured in increments of 1×10^{-18} uCi/mL from 1 to 10, and above 10 contours are omitted and raw data values are presented, because air concentrations at Mound are so high that contours near the lab are too close together. Figure 3 shows that air dispersion of the heavy metal and radionuclide Pu²³⁸ extends into Miamisburg, as was also shown in Figure 1.

Figures 1 and 3 both show that the heavy metal Pu²³⁸ was dispersed through the air, off-site from Mound Lab into the surrounding area. Miamisburg, especially north, east, and to a lesser extent west of Mound, received airborne fallout of heavy metals and radionuclides from Mound.

Mound Lab emitted relatively little Pu²³⁸ in 1997 compared to earlier years. The year 1997 was chosen for this illustration not because of the high Pu²³⁸ airborne emissions, but because by 1997 Mound Lab had a relatively thorough air monitoring system in place. Figure 4 shows a graph of annual Pu²³⁸ air emissions from Mound Lab for 1960 - 1998. Table 2 gives data that were graphed to construct Figure 4. Note that Pu²³⁸ emissions for most years are not even seen on this plot because most years emissions of Pu²³⁸ from Mound were relatively small compared to the huge emissions in 1960, and relatively large emissions from 1965 to 1970. If we were to scale Figures 1 and 3 up to the higher emissions during the 1960's and assume that non-radioactive heavy metals were also emitted from Mound Labs, then we can easily account for the presence of both radionuclides and heavy metals in elevated concentrations in the groundwater of Parcel 4.

Response:

The assertion that the potential source of elevated metals in the groundwater associated with Parcel 4 is the result of air deposition is interesting. The concentrations of metals and radionuclides listed in Table 2.9 are from groundwater monitoring across the Mound Plant (See Appendix B of the RRE). Most of the highest values are from the bedrock monitoring wells located north of Parcel 4, in the main process areas. If air deposition was the main source of elevated groundwater metals, a very significant overall increase in soil metals concentrations throughout the entire Mound site would have been detected. It has not. Also, an increasing trend in groundwater metals concentrations in all shallow monitoring wells should have emerged if the contamination was distributed by air and has migrated to the deeper monitoring wells. No such trends have been observed.

Figure 2. Location of air monitoring stations July 1992 to May 1993

Plutonium emission figures for 1960 to 1989 were found in the Remedial Investigation/Ferrous Study, Operable Unit 2, site-wide work plan, Revised May 91 DOE, Section 2, page 6. Plutonium emission figures for 1990 through 1998 were found in the yearly Annual Site Environmental Reports 1990 through 1998.

- 3) It appears that the source of the elevated radionuclides and heavy metals in the groundwater at Parcel 4 is air emission from Mound Lab. Therefore, levels of heavy metals and radionuclides in the groundwater in Miamisburg adjacent to Mound Labs are probably elevated and of environmental concern. Groundwater studies similar to Parcel 4 should occur in Miamisburg.

Response:

As discussed above, the results listed in Table 2.9 are from bedrock monitoring wells from across the entire Mound Plant. Many wells with the elevated levels of heavy metals are located in or just down gradient of the process areas north of Parcel 4 (see Appendix B of the RRE). Additional investigation is underway as discussed earlier.

There is an offsite groundwater monitoring program at Mound. It's objectives are to assure local residents and communities that their drinking water has not been adversely impacted by plant activities and to provide an early warning of impacts due to continuing environmental restoration activities. This program consists of the collection and analysis of samples from production wells, private wells, regional drinking water supplies, and BVA monitoring wells. Samples are analyzed for radionuclides, inorganic substances, and VOCs. The details of the program and its results are available in the Annual Environmental Monitoring Report. In 1999, the average tritium concentrations ranged from 0.05nCi/L to 0.53 nCi/L (with the MCL = 20nCi/L). Many results for other radionuclides were comparable to background levels; average concentrations were less than 2.9% of the respective dose standard.

The Mound Core Team
P.O. Box 66
Miamisburg, Ohio 45343-0066

Rev. Dr. Velma M. Shearer
124 Chestnut Street
#210
Englewood, Ohio
45322

Dear Rev. Dr. Shearer:

The Core Team, consisting of the U.S. Department of Energy Miamisburg Environmental Management Project (DOE-MEMP), U.S. Environmental Protection Agency (USEPA), and the Ohio Environmental Protection Agency (OEPA), appreciates your comments on the Proposed Plan for Parcel 4. Attached are our responses.

Should the responses to comments require additional detail, please contact Rob Rothman at (937) 865-3823 and we will gladly arrange a meeting or telephone conference.

Sincerely,

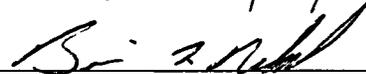

DOE/MEMP:

Robert S. Rothman, Remedial Project Manager

USEPA:

Timothy J. Fischer, Remedial Project Manager

OEPA:

Brian K. Nickel, Project Manager

**Comments Received on the
Parcel 4 Proposed Plan and Risk Evaluations
from
Rev. Dr. Velma M. Shearer
January 2001**

Concerns:

1. The drainage from PRS 419, the drainage pipe along the western boundary of the Mound Site and which ends within Parcel 4, before draining by open concrete ditch across City Park property to the Great Miami River.

It has been stated that the effluent which drains through the pipeline is run-off from the overflow ponds to the north, and this is monitored at Outfall 002 daily for gross alpha (and tritium) and biweekly from 24 hour composite samples for Pu 238, Pu 239/240, U 233/234, U 238, Th 228, Th 230, and Th 232. Will this effluent become the source of water for the future pond as shown within the drawings for future development of parcel 4? Or, if the effluent is routed permanently through the open concrete ditch to the Great Miami River, it should be monitored and released only to meet recreational standards rather than industrial standards. Add to the recreational standard a factor of 10 for children under 15 years of age, since children are much more susceptible to carcinogens than adults. This is not considered in the Proposed Plan, but is, in reality, located on the edge of Parcel 4.

Response:

The effluent from PRS 419 (Drainage Outflow Reroute) does come from the site's drainage system. This system includes the Retention Basins, the Overflow Pond, Outfall 002, the drainage ditch that separates the two hills that comprise the site, and the Asphalt-lined Pond. The effluent at Outfall 002 is regulated by the site's National Pollutant Discharge Elimination System (NPDES) permit. Sampling for radionuclides is not required by the NPDES permit; however flow-proportional samples are collected from Outfall 002 and are analyzed for tritium and isotopes of plutonium, uranium, and thorium. Samples are collected daily during the work week. Three 24-hour samples are collected on Tuesdays, Wednesdays, and Thursdays. One 96-hour sample is collected each Monday. Samples are analyzed four times a week for tritium. Two-week composite samples are analyzed for isotopes of plutonium and uranium. The two-week composite samples are also analyzed for isotopes of thorium. The results of these measurements are reported in the Annual Site Environmental Monitoring Report. According to MMCIC's current

plans, this effluent will not be the source of water for the future pond planned for Parcel 4.

The second part of your concern addresses the standards employed in monitoring this effluent (industrial vs. recreational). These are scenarios for calculating risk. Standards with different bases are applied to this effluent. The nonradioactive constituents in this effluent are monitored and regulated by the NPDES permit limits. The radioactive constituents are compared to Derived Concentration Guides (DCGs). These are the concentrations that would result in a 50-year committed effective dose equivalent of 100 mrem. DCGs are listed in DOE Order 5400.5 and are based on recommendations in Publications 26 and 30 of the International Commission on Radiological Protection. The DCGs for water are based on the conservative assumption that the water is used as drinking water; clearly not the case for this effluent. The average radionuclide concentrations at Outfall 002 during 1999 were:

Radionuclide	Average Concentration MicroCurie/mL	Average as a percent Of DOE DCG
H-3	2.14E-6	0.11
Pu-238	4.82E-10	1.21
Pu-239	4.45E-12	0.015
U-233,234	5.15E-10	0.1
Th-228	5.3E-11	0.01
Th-230	2.6E-11	0.009
Th-232	3.67E-12	0.007

2. The total and incremental carcinogenic and non-carcinogenic risks exceed the acceptable risk range for the future construction worker and the future site employee due to potential exposure groundwater.

Though the estimates for future exposures are biased high, yet considerable PRS cleanup is yet to take place across the site, and must be included in the calculations. For example, a number of PRSs exist which can contribute potential exposure through the movement of the groundwater to the Buried Valley Aquifer: the Pu 238 and Th contaminated soils disposed at the disposal area known as Rader's Hill, the sampling locations I8, I9, J8 and J9 in the region of Building 21 and upgradient areas east of this site, and the Thorium 230 samples taken very near to the Parcel 4 north boundary and which exceeded the 3.0 pCi/g industrial site limit. Though a barrier may delay some of the transport, we must keep in mind that Pu 238 can attach to colloids and move with the colloids in water, and that the Th 230 could be in a water soluble form and thus move with the groundwater flow. (See the following

published papers which give examples of radionuclide transport by natural organic matter from its original deposition to other areas.)

- a) A. B. Kersting, D.W. Eford, D. L. Finnegan, D. J. Rokop, D. K. Smith and J. L. Thompson, "Migration of Plutonium in Ground Water at the Nevada Test Site", *Nature*, Vol. 397, 7 January 1999, 58-59.
- b) John F. McCarthy, William E. Sanford, and Paige L. Stafford, "Lanthanide Field Tracers Demonstrate Enhanced Transport of Transuranic Radionuclides by Natural Organic Matter", *Environmental Science & Technology*, Vol. 32, No. 24, December 15, 1998, A-F.
- c) Richard C. Marty, Deborah Bennett, and Philip Thullen, "Mechanisms of Plutonium Transport in a Shallow Aquifer in Mortandad Canyon, Los Alamos National Laboratory, New Mexico", *Environmental Science and Technology*, Vol. 31, No. 7, 1997, 2020-2027.

Since the existent potable water source wells on the Mound site are not to be used as a water resource for the newly established industries in Parcel 4, and since the most likely source of potable water for Parcel 4 industrial use will be the Miamisburg City water wells which also draw from the same Buried Valley Aquifer, and since the Miamisburg wells are sufficiently close to the Parcel 4 perimeter, the question remains as to how long before these wells also will be of concern. The Miamisburg City water wells are already known to contain 300 pCi/L of tritium.

Response:

The references listed point out that movement of radionuclides in the subsurface is possible by colloidal transport or through complexation with naturally occurring organic matter. Although this is a possible avenue of migration for elements with normally high affinities to soil (i.e. thorium & plutonium), it does not appear to be a predominant transport mechanism at Mound. For example, if thorium or plutonium were present in the groundwater and migrating in significant concentrations as colloids or organic complexes, samples from monitoring wells directly down-gradient of disposal sites containing these contaminants should consistently show measurable concentrations above background. Such trends have not appeared in over a decade of extensive groundwater monitoring. Although details of the groundwater monitoring program to be implemented as part of the Stewardship efforts at the Mound are yet to be established, correctly placed "sentinel" wells near disposal areas containing radionuclides will help confirm that these contaminants remain immobile. Parcel 4 contains

no disposal areas, providing further assurance that colloidal transport or organic complexation of radionuclides is not a potential long-term liability at this site.

The last paragraph of the comment expresses concern for the potential migration of contaminants from Parcel 4 to the current Miamisburg wellfield. In 1995, the DOE completed a detailed numeric groundwater model of the Great Miami River Buried Valley Aquifer (*Operable Unit 9, Determination of Potential Pathways from Source Areas Adjacent and Within the Buried Valley Aquifer via Ground Water Flow Modeling and Particle Tracking. Technical Memorandum, Final, September 1995*). This model substantiated that the Miamisburg wellfield zone of capture is strongly influenced and limited by recharge from the Great Miami River. Due to this recharge, the position of the Miamisburg wellfield nearly a mile up-gradient of Parcel 4 and the groundwater capture zone created by the Mound production wells, the potential for adverse contaminant impact is remote.

3. The cumulative Cancer Risks for all carcinogenic contaminants do not appear to include Cr(VI) (Hexavalent Chromium) and Sb (Antimony). Cr(VI) is a confirmed human carcinogen; Sb is a questionable carcinogen with experimental carcinogenic data. Both of these chemicals should be included the Cancer Risk calculations. The Cancer Risk totals, hopefully, includes both radiological and hazardous contaminants in the total calculations.

Response:

In general, we total risk for both radioactive and non-radioactive carcinogens.

The *Mound 2000 Residual Risk Evaluation Methodology (RREM)* indicates that the process of evaluating residual risk starts with a list of constituents that includes every compound detected in a given media. These constituents are then screened using criteria established by the RREM to determine which constituents are carried through the RRE. Using the constituent screening methods put forth in the RREM, antimony was retained as a constituent of potential concern (COPC) for groundwater and soil greater than 2 feet below land surface (bls), but not for soil 0-2 feet bls. The level of antimony detected in soil 0-2 feet bls was lower than the screening guideline value. Therefore, antimony was not carried through the RRE calculations for this media. The non-carcinogenic effects of antimony in soil greater than 2 feet bls and groundwater were evaluated in the RRE.

Antimony has not undergone a complete evaluation under US EPA's Integrated Risk Information System (IRIS) program for evidence of human carcinogenic potential. Therefore, the carcinogenic potential of antimony could not be evaluated. However, according to U.S. EPA, multimedia antimony exposures (exposures that occur outside the workplace) are essentially negligible by comparison to occupational exposures where discrete clinical health effects have been observed (*Ambient Water Quality Criteria Document for Antimony*. Prepared by the Office of Health and Environmental Assessment, Environmental Criteria and Assessment Office, Cincinnati, OH for the Office of Air Quality Planning and Standards, Washington, DC. EPA 440/5-80-020). Therefore, incidental exposures to antimony are not likely to cause unacceptable levels of risk.

Total chromium was evaluated in site media and was conservatively assumed to be present in the hexavalent state. Using the constituent screening methods specified by the RREM, Chromium VI was not retained as a COPC in current groundwater, soil 0-2 feet bls or soil greater than 2 feet bls. In all three instances, chromium was detected at levels below the Chromium VI guideline values. Chromium VI was carried through the screening process for Future Groundwater in both the Construction Worker and Site Employee scenarios. For the ingestion pathway, IRIS does not provide a cancer slope factor for Chromium VI due to lack of evidence. IRIS does provide an inhalation cancer slope factor for Chromium VI. Metals in general were removed from the inhalation pathway since they do not readily volatilize from water while showering. Hence, Chromium VI was removed from consideration as a carcinogen because the pathway (inhalation) to the receptors (Construction Worker, Site Employee) did not exist. A copy of the ATSDR factsheet for chromium is enclosed.

4. Are emergency plans in place for an unforeseen overflow of the holding ponds in case of a heavy rainfall, especially if, for example, during a time when serious remediations are taking place, e.g., of PRS 66? How would such an overflow effect the 419 pipeline and its exit at the Parcel 4 border?

Response :

Contingency plans exist for managing the Overflow Pond in the case of a release and for stormwater management/erosion control during remediation activities. In the event of a (suspected) release, a gate just upstream of the Retention Basins is closed; this diverts the drainage to the Overflow Pond. This pond has approximately four million gallon capacity

and can hold approximately two weeks of the site's water effluent if there is no rain. If the Overflow Pond should exceed its capacity, the overflow travels to the west from the southern corner of the pond, crosses the road, and pools on the DOE property. The overflow from the pond would not enter the drainage reroute (PRS 419).

Stormwater management/erosion control measures for remediation projects are designed specifically for each project. Heavy rainfall on site during remediation activities has always been a prime concern. Note that during remediation of the canal, OEPA recommended additional controls for potential run on flows. These were constructed upgradient of the project. Additionally, the project was constructed and managed in a manner that considered rainfall and as a result there were no unplanned releases during the extensive remediation process. Recall that the reason for the cleanup of the canal was a storm event washing contamination off site, and the site was reminded of this to emphasize the importance of stormwater controls during remediation of the canal. OEPA was very pleased with the result. It is our intent to see that the proper controls are placed during all remediation activities, and in particular PRS 66. The site has already been talking about controls such as those to prevent run on into the disturbed soil areas, and using the excavation itself to contain any storm flows that come in contact with disturbed earth. Then the water can be removed under controlled conditions (tested, pumped for appropriate disposal, etc). This method has been used in some of the removals on this and other sites and works well.

5. A cost of approximately \$5000 annually is proposed for the maintenance of deed restrictions, Institutional Controls and maintenance for the total former Mound site. Who will be funding any needed monitoring of water, soils, and air on Parcel 4? Certainly an additional amount should be provided annually for a basic environmental monitoring program.

Response:

The \$5,000 per year as referenced is the annual estimated cost for maintaining the Institutional Controls for Parcel 4 (i.e. deed restrictions) and performing the effectiveness reviews for US EPA and OEPA as described in the Proposed Plan. The selected remedy for Parcel 4 does not include monitoring of water, soils, or air on Parcel 4. However, as the Exit Project continues, DOE will continue its environmental surveillance program. This program and its results are described in the Annual Site Environmental Monitoring Report. Any monitoring of the site after DOE completes its mission would be part of Post Closure Stewardship and may be included in the site-wide Proposed Plan and Record of Decision. As a

member of the Post Closure Stewardship Committee, you know these discussions are just beginning.

6. Where will a Data Base be established, and who will maintain all records? This could become part of the Stewardship Program, however, an additional dimension-specific to Parcel 4 would need to be added.

Response:

If the contents of the Data Base are the results of monitoring discussed in Comment 5, the Stewardship Program is the appropriate vehicle to address the question. DOE will retain responsibility for and ownership of the information in the current data base (Mound Environmental Information Management System or MEIMS) and the Geographic Information System.

EXECUTIVE SUMMARY

The Mound Plant in Miamisburg, Ohio is operated for the U.S. Department of Energy (DOE) by BWXT of Ohio, Inc. (BWXTO). The plant started in operation in 1949 as an integrated research, development, and production facility operating in support of the DOE weapons and energy program (DOE, 1994). DOE purchased the area immediately south of the Mound Plant in 1981. This area, known as the South Property, consists of 124-acres of former farmland. Parcel 4 consists of approximately 95 acres of the South Property. Since its purchase, access to the South Property and Parcel 4 has been restricted, and the only notable disturbances have been periodic mowing of grassy areas and occasional field training exercises by the Mound Plant security force. No plant operations occurred on the property, though the property did receive surface runoff from the adjacent operations that has potentially contaminated Parcel 4. The boundary of Parcel 4 was defined in 1999 to exclude an area of known contamination.

This screening level ecological risk assessment (SLERA) has been prepared for Parcel 4 as part of RI/FS activities at the plant. The overall objective of the SLERA is to determine whether Mound Plant-related contamination poses a current or potential threat of adverse ecological effects to ecological receptors inhabiting Parcel 4. In support of the SLERA, a site walkthrough survey was conducted on 20 and 21 March 2000. This qualitative survey was primarily designed to gather information on changes in general habitat cover since the 1992/1993 OU-9 Ecological Investigation, and to assess the potential for occurrence of several receptor species for evaluation in the SLERA.

This SLERA consists of the following two steps:

- Screening-Level Problem Formulation and Screening-Level Ecological Effects Evaluation.
- Screening-Level Preliminary Exposure Estimate and Risk Calculation.

PROBLEM FORMULATION

The screening-level problem formulation step focuses on identifying categories of potential ecological receptors that may exist in the site area; identifying contaminants which may pose unacceptable risk to those receptors; and determining contaminant fate/transport and toxicity mechanisms (EPA, 1996).

Careful examination of all habitats on Parcel 4 during the March 2000 walkthrough survey revealed minor changes in certain habitat categories related to succession of the plant communities. However, no significant physical changes have occurred since completion of the Operable Unit 9, Ecological Characterization study. The habitats present on Parcel 4 include:

-
- Mesic grassland.
 - Subxeric grassland.
 - Low gradient upland forest dominated by south and west aspects.
 - Low gradient upland forest with level or nearly level topography.
 - Early successional scrub/shrub.
 - Late successional scrub/shrub.

There are no permanent streams on the site, although during prolonged wet periods, there is flow in the unnamed, intermittent stream channel that enters Parcel 4 from the property south of Benner Road. Seasonal groundwater seeps are also present on the property. While the site lies within the range of several federal/state threatened and endangered species, no listed species is expected to be a permanent, year-round resident of Parcel 4.

There were no known direct releases of site contaminants to Parcel 4, though there is the potential for past on-site releases to migrate onto the property primarily through surface water runoff. Several characterization investigations have been conducted on Parcel 4 to determine the extent of contaminant migration to this adjacent property. PRS 306 is a groundwater seep; PRS314 is an area that contained farm trash and potentially oil from previous farm operations; and PRS 406 is at the northern end of Parcel 4 near Mound Plant and may contain radiological contamination.

Several target terrestrial receptors from several trophic levels (i.e., herbivores and insectivores) were selected to represent animal populations that inhabit the site and the surrounding areas. The selected target species have been observed on Parcel 4 during all sampling seasons, represent several guilds, and are commonly used as receptors of concern in ecological risk assessments. Direct contact with soil by plants, earthworms, and soil-dwelling organisms was evaluated, as well as exposure to surface water and sediment in Benner Branch by aquatic organisms.

Plutonium-238 and other radionuclides in soil, surface water, and sediment above site-specific background levels are considered to be radiological constituents of potential concern (COPCs). To determine chemical COPCs in soil, surface water, and sediment, the maximum detected concentration of a contaminant was compared to ecological screening levels and site-specific background levels. Chemical COPCs included several organics, numerous inorganics, and one anion.

ECOLOGICAL EFFECTS EVALUATION

For each COPC with a potentially complete exposure pathway, a screening-level toxicity reference value (TRV) was developed from a review of literature. TRVs based on dose are used for bird and mammal receptors and TRVs based on media concentrations are used for plants, earthworms, soil-dwelling organisms, aquatic organisms, and benthic organisms. For chemical COPCs, the TRV is based on the chronic NOAEL for a constituent obtained from literature

source. For radionuclides, the International Atomic Energy Agency (IAEA) recommends limiting the dose for terrestrial organisms to 100 mrad/day (IAEA, 1992; Sample et al., 1997). This dose limit is based on studies evaluating reproductive success and survival. A dose rate of 1 rad/day is generally considered protective of plant and invertebrate populations (IAEA, 1992; Barnhouse, 1995; Sample et al., 1997). The recommended acceptable dose rate to natural populations of aquatic biota is 1 rad/day based on results of the reviews summarized in NCRP Report No. 109 (NCRP 1991; BJC, 1998). This limit was intended to apply to the most radiosensitive populations of aquatic organisms (BJC, 1998).

EXPOSURE ESTIMATE

Birds, such as the American robin and northern cardinal, and mammals, such as the meadow vole, short-tailed shrew, and white-tailed deer, which represent several trophic levels, were selected as target receptors. Direct ingestion of COPCs in soil and surface water, and indirect ingestion through the food chain via ingestion of plants and insects were considered in this assessment. External exposure through direct radiation from soil and inhalation of radionuclide-contaminated dust were also considered for radiological COPCs. Direct impacts on plants, earthworms, soil-dwelling organisms, aquatic organisms, and benthic organisms were evaluated for both chemicals and radionuclides.

To estimate radionuclide exposure by ecological receptors (i.e., plants, earthworms, and terrestrial wildlife), a radiation dose rate in millirads per day (mrad/d) was calculated for each receptor group following the methodology described in *Methods and Tools for Estimation of the Exposure of Terrestrial Wildlife to Contaminants* (Sample et al., 1997). Exposure routes evaluated for radionuclides include external exposure through direct radiation from soil (both aboveground and below ground) and internal exposure through ingestion of soil, prey, and water and through inhalation of contaminated dust.

To estimate chemical exposure by avian and mammalian ecological receptors, exposure doses were estimated for the selected target species from soil concentrations using species-specific food and soil ingestion rates, literature-based bioconcentration factors to estimate chemical concentrations in food, and species-specific body weights. To ensure that sites which may pose an ecological risk are properly identified, exposure values were biased in the direction of overestimating risk. To estimate chemical exposure by plants and soil-dwelling organisms, soil concentrations were compared to literature benchmarks for these organisms.

Using methods developed by Blaylock et al. (1993), Bechtel Jacobs Company (1998) has developed benchmarks for radionuclides in sediment and surface water that result in a total dose rate of 1 rad/day for fish. These benchmarks were used to estimate radionuclide exposure by aquatic life in Benner Branch and from groundwater discharge to surface water.

RISK CALCULATION

The hazard quotient (HQ) approach was used as an indicator of the risks posed to surrogate ecological receptors from exposure to site-related contaminants. The hazard quotient compares exposure values to dose-based or media-based TRVs, and can be expressed as the ratio of a potential exposure level to the TRV. A hazard quotient exceeding 1.0 indicates the species of

interest (or the species for which the toxicity data was based on) may be at risk of an adverse effect from the particular COPC, exposure route, or medium on which the HQ was based. Further evaluation may be needed in terms of site-specific toxicity data for a given target receptor.

While there is potential risk to plants, earthworms, and soil-dwelling organisms exposed to chemical COPCs in soil and to aquatic receptors exposed to chemical contaminants in the intermittent natural drainage channel on Parcel 4, this risk is minimal. Many of the chemical COPCs may be present due to naturally occurring or anthropogenic sources.

The conservative screening level ERA found that there is a potential for adverse effects on terrestrial organisms from residual chemical contamination (i.e., metals). However, refinement of the preliminary COPCs found that the potential for adverse ecological effects due to site-related waste disposal activities is low. The refinement included a background evaluation, recalculation of HQs using an average exposure point concentration (i.e., 95% UCL), evaluation of bioavailability of COPCs, adjustment of the area use factor, and a re-evaluation of ecological screening levels.

1.0 INTRODUCTION

The Mound Plant in Miamisburg, Ohio is operated for the U.S. Department of Energy (DOE) by BWXT of Ohio, Inc. (BWXTO). Figure 1-1 shows the location of the Mound Plant in relation to surrounding cities. The plant started in operation in 1949 as an integrated research, development, and production facility operating in support of the DOE weapons and energy programs (DOE, 1994). DOE purchased the area immediately south of the Mound Plant on August 26, 1981. This area, known as the South Property, consists of 124-acres of former farmland. Parcel 4 consists of approximately 95 acres of the South Property. The northern border of Parcel 4 is about 400 feet south of the on-site road that forms the boundary of the South Property. Since its purchase, access to the South Property and Parcel 4 has been restricted, and the only notable disturbances have been periodic mowing of grassy areas and occasional field training exercises by the Mound Plant security force. No plant operations occurred on the property, though the property did receive surface runoff from the adjacent operations that has potentially contaminated Parcel 4.

This screening level ecological risk assessment (SLERA) has been prepared for Parcel 4. The overall objective of the SLERA is to determine whether Mound Plant-related contamination poses a current or potential threat of adverse ecological effects to ecological receptors inhabiting Parcel 4. In support of the SLERA, a site walkthrough survey was conducted on 20 and 21 March 2000. This qualitative survey was primarily designed to gather information on changes in general habitat cover since the 1992/1993 OU-9 Ecological Investigation, and to assess the potential for occurrence of several receptor species for evaluation in the SLERA.

A preliminary or screening-level risk evaluation is the initial ecological risk assessment screening at a hazardous waste site (EPA, 1996). EPA (1997) defines a SLERA as “a preliminary risk assessment that can be conducted with limited site-specific data by defining assumptions for parameters that lack site-specific data.” To ensure that sites that may pose an ecological risk are properly identified, EPA (1997) suggests that “values should be consistently biased in the direction of overestimating risk. Without this bias, a screening evaluation could not provide a defensible conclusion for an absence of ecological risk.” In conjunction with the human health risk assessment, the ecological risk assessment forms the basis for determining the need for remedial activities at a site and serves as the justification for the selected remedial action.

Technical risk assessment guidance for the performance of the screening-level ecological risk assessment came primarily from:

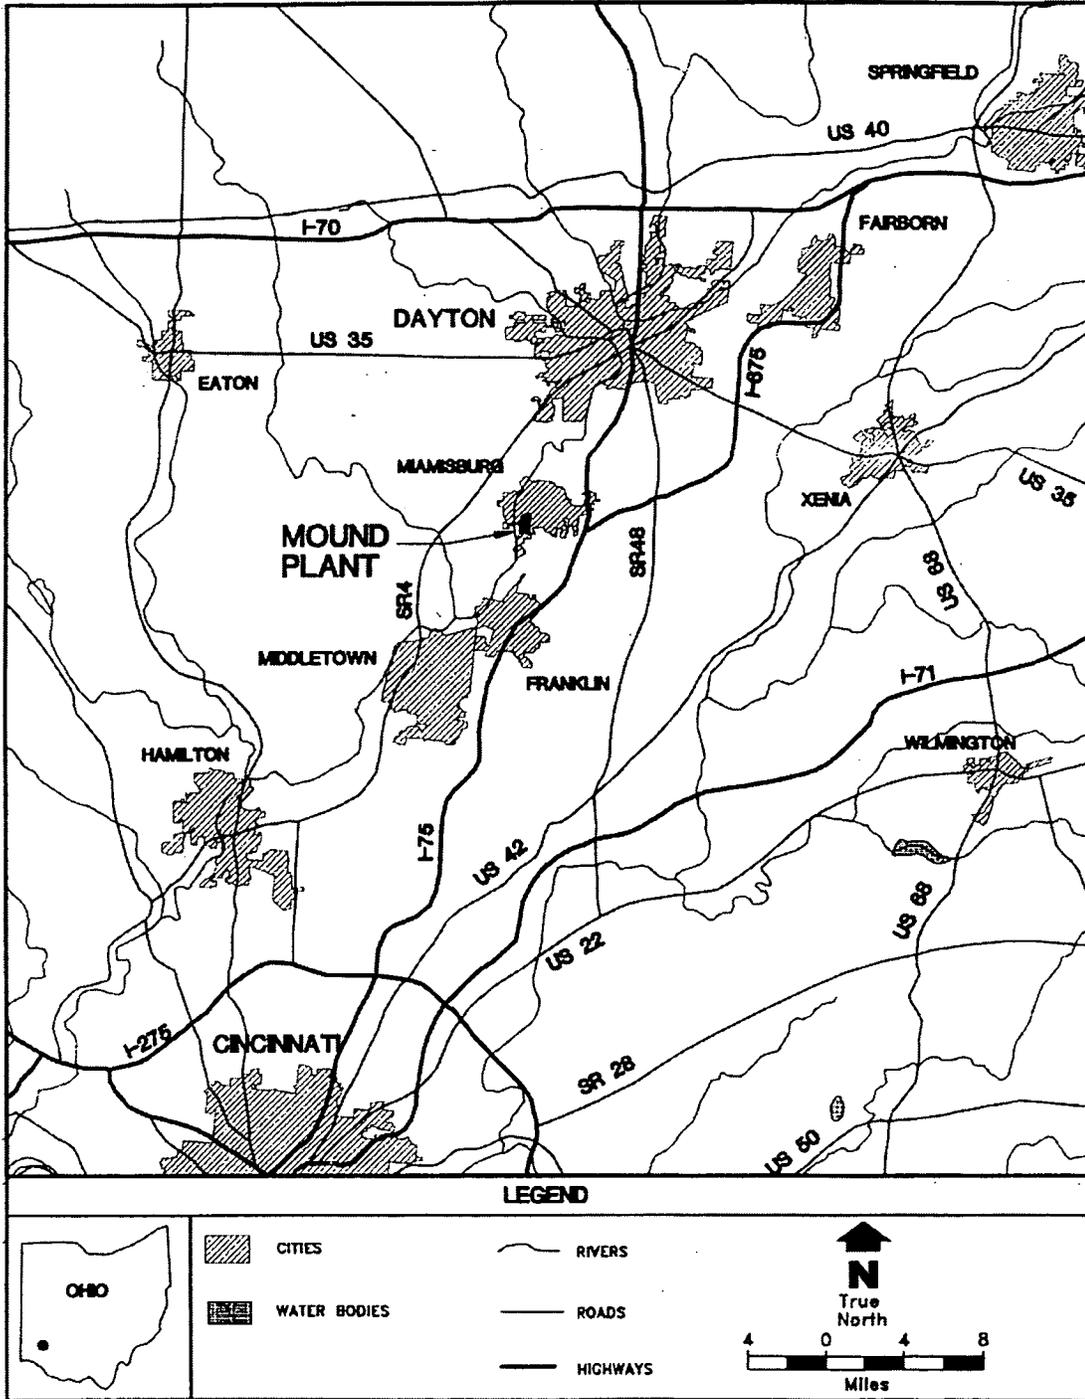

- *Ecological Risk Assessment Guidance for Superfund: Process for Designing and Conducting Ecological Risk Assessments* (EPA, 1997).
- *Guidelines for Ecological Risk Assessment* (EPA, 1998).

This screening-level ecological risk assessment consists of the following two steps:

- Screening-Level Problem Formulation and Screening-Level Ecological Effects Evaluation.
- Screening-Level Preliminary Exposure Estimate and Risk Calculation.

Each step of the screening-level ecological risk assessment for Parcel 4 is presented in the following sections.

**Figure 1-1
Mound Plant Location**

2.0 SCREENING LEVEL PROBLEM FORMULATION

The screening-level problem formulation step focuses on identifying categories of potential ecological receptors that may exist in the site area; identifying contaminants which may pose unacceptable risk to those receptors; and determining contaminant fate/transport and toxicity mechanisms (EPA, 1996). A planning step then identifies the major factors (i.e., environmental setting, extent of contamination, contaminant fate and transport, potential receptors, and complete exposure pathways) to be considered in the screening-level ecological risk assessment.

2.1 Environmental Setting

The following subsection on the environmental setting is summarized from information presented in the *Operable Unit 9, Ecological Characterization Report* (DOE 1994). In addition, observations made during a site visit on 21 and 22 March 2000 are also discussed.

2.1.1 Site History

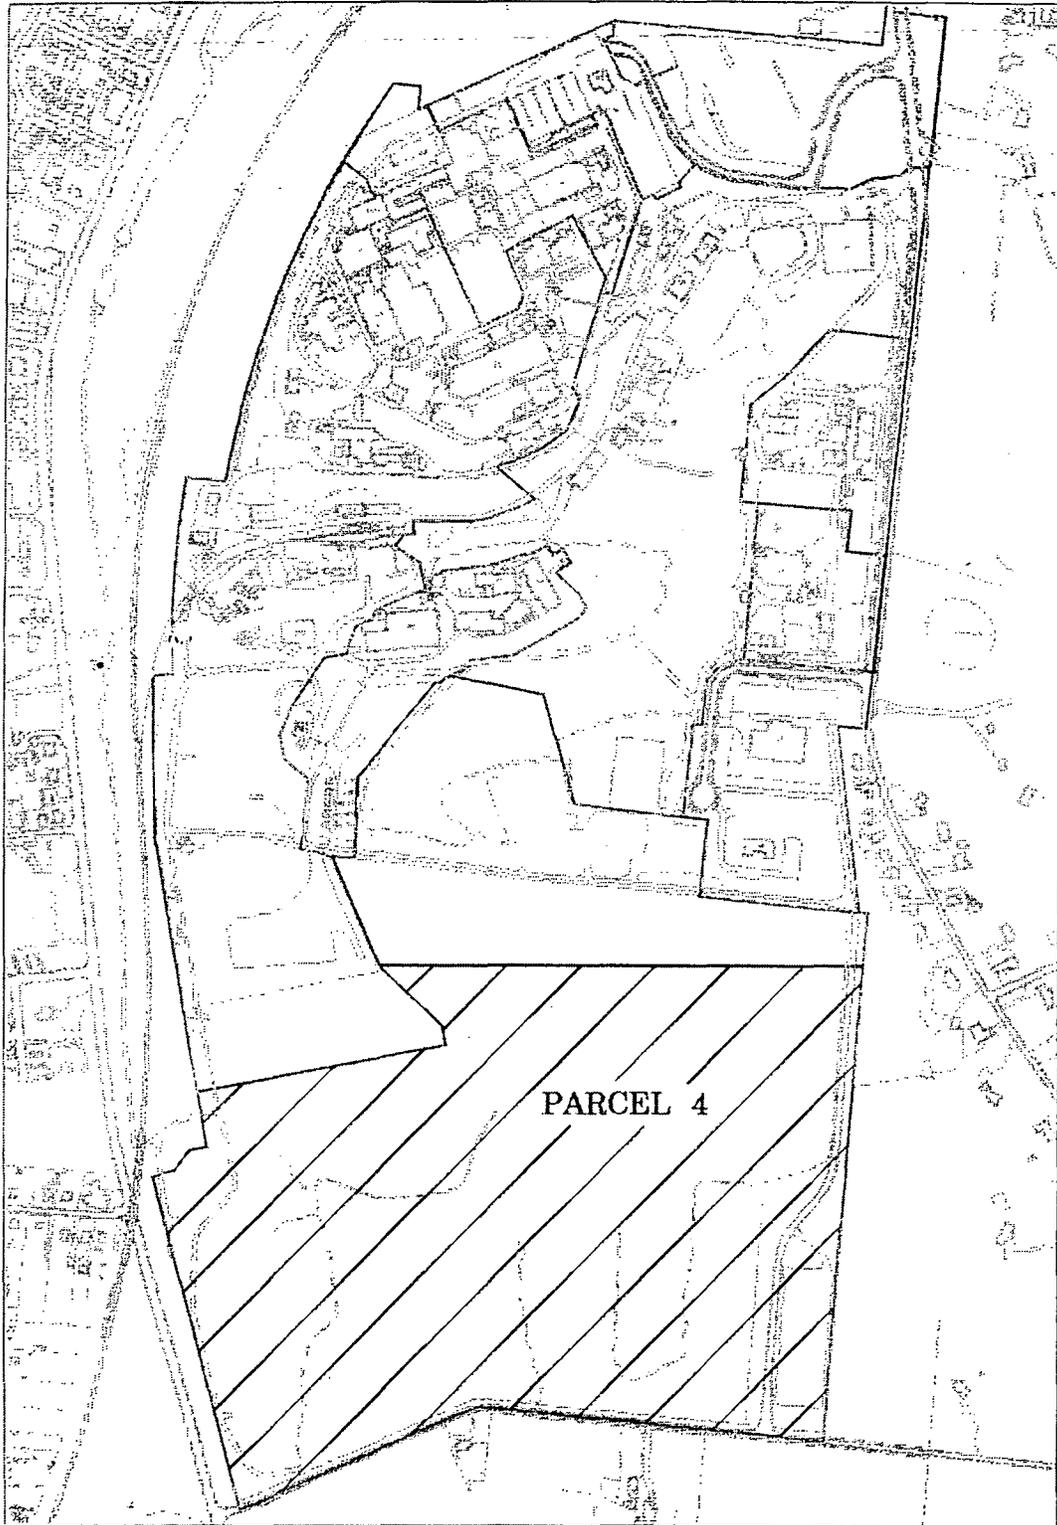

The Mound Plant (Figure 2-1) was established in 1946 on a 728,000 square-meter (m²) (182-acre) untillable portion of a farm consisting of two large hills with a northeast-southwest trending valley separating them. The Mound Plant is located in the Eastern Deciduous Forest Province in the transition zone between the beech-maple forest and oak-hickory forest plant associations (Bailey, 1978).

Land use in the areas to the north, east, and west of the Mound Plant is largely residential with relatively low population density.

DOE purchased the area immediately south of the Mound Plant in 1981 (i.e., the South Property). The 124-acre South Property is bounded by Mound Plant to the north, private property to the east, Benner Road to the south, and the Miami-Erie Canal to the west. The land, which is gently rolling until the Mound Plant property line where it is steeply sloped, was used for agricultural purposes. DOE razed a two-story brick house, a barn, a frame tool shed, and an outhouse, disposed of some old implements, and discarded appliances that were left by the former owner. A farm fence was put up around the perimeter. Since its purchase, access to the property has been restricted, and the only notable disturbances have been periodic mowing of grassy areas and occasional field training exercises by the Mound Plant security force.

The 124 acres were originally in Operable Unit 5, though subsequently the land was divided into release block A and release block B. In 1999, the north property line was shifted slightly and the property is now called Parcel 4. The current boundary of Parcel 4 is shown in Figure 2-1. Parcel 4 consists of approximately 95 acres of the original 124 acres. No plant operations, no spills or

Figure 2-1
Site Location Map

releases to the environment from the Mound Plant, and no dumping activities occurred on the property. The property did receive surface runoff from the adjacent plant operations, which has potentially contaminated Parcel 4. PRS 306, PRS 314, and PRS 406 are located in Parcel 4. PRS 306 is a groundwater seep; PRS 314 is an area that contained farm trash and potentially oil from previous farm operations; and PRS 406 is at the northern end of Parcel 4. The new property risk assessment concluded that no further assessment was needed for PRS 306, PRS 314, and PRS 406 (DOE, 1996a).

2.1.2 Site Description

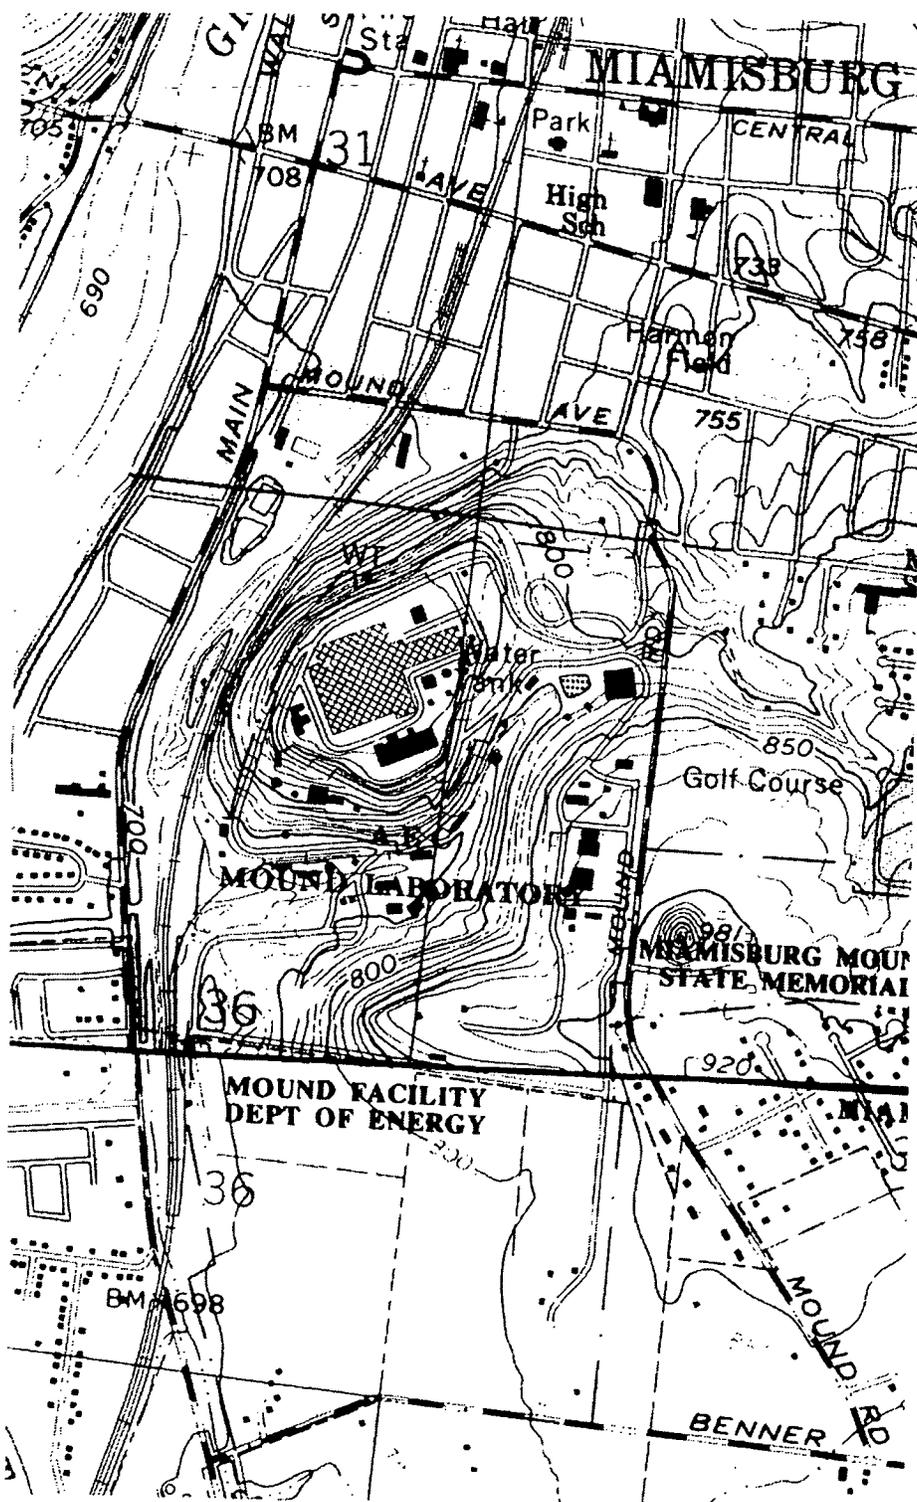

Parcel 4 is bounded by Benner Road to the south, and the Contractor's Entrance Road to the east and to the west by the Miami-Erie Canal. The north boundary is approximately 400 feet south of the Mound Service Road. In general, Parcel 4 slopes from east to west. Elevations range from 890 ft (above sea level) in the northwest corner to approximately 700 ft. along most of the western boundary. Figure 2-2 is a US Geological Survey map for the entire Mound Plant.

There are no permanent streams on the site, although during prolonged wet periods, there is flow in the unnamed, intermittent stream channel that enters Parcel 4 from the property south of Benner Road. For ease of reference, this channel was called the Benner Branch in *Operable Unit 9, Ecological Characterization Report* (DOE 1994). When water is present, Benner Branch flows north onto the site, receives input from numerous swales draining the west and north-facing slopes of Parcel 4, turns west near the center of Parcel 4, then flows westward to the western site boundary. Ultimately, this channel flows into the southern section of the Miami-Erie Canal in the vicinity of the Norfolk Southern Railroad trestle over Dayton-Cincinnati Pike. Throughout Parcel 4, the natural drainage channel is intermittent, and does not sustain surface flow except during heavy precipitation events. During prolonged wet periods, Benner Branch can carry a substantial amount of flow, as evidenced by observations of high water after heavy rains during the *Operable Unit 9 Ecological Characterization* (DOE 1994). This was supported by observations made during fieldwork for this report, of water-borne debris lodged in overhanging tree limbs several feet above the channel. On 21 March 2000, Benner Branch carried strong flow, estimated at several cubic feet per second. Most of the swales and channels draining the north-and west-facing slope of Parcel 4 carried water on that day. However, the following day, the main channel draining the north-facing slope had flow only in the upper reaches. The lower reaches were dry, indicating water was leaving the surface and entering the water table through porous media. The USGS Franklin quadrangle topographical map does not show the channel on Parcel 4, but shows the larger, unnamed, intermittent stream that it drains into (Figure 2-2). Eight groundwater seeps have been identified within Parcel 4. These seeps are primarily located in the north – northeastern half of Parcel 4. These seeps or springs can generally be described as surface expressions of groundwater flow and their presence is seasonal.

2.1.3 Site Ecology

The Mound Plant, including Parcel 4, is located in the Eastern Deciduous Forest Province in the transition zone between the beech-maple forest and oak-hickory forest plant associations (Bailey 1978). An ecological characterization study was conducted during 1992-1993 for Operable Unit

Figure 2-2
USGS Map

9, which consisted of site-wide studies of the Mound Plant and off-site areas. The objectives of this study were to: 1) identify flora and fauna in and around the site; 2) identify sensitive environments in and around the site; and 3) identify endangered species and their habitats in and around this site. Field surveys included floristic sampling, bird, mammal, herptile trappings and surveys; and fish and macroinvertebrate sampling and surveys. The results of this study are presented in the *Operable Unit 9, Ecological Characterization Report* (DOE, 1994). The reader is referred to this document for the detailed results of this study.

In support of this ecological risk assessment, habitats on Parcel 4 were delineated and re-examined on 21 and 22 March 2000 with the aid of recent aerial photographs and maps from the *Operable Unit 9, Ecological Characterization Report* (DOE 1994). The March walkover was primarily designed to gather information on changes in general habitat cover since the OU-9 Ecological Investigation, and to assess the potential for occurrence of several receptor species for evaluation in the SLERA. The WESTON ecologist who directed the original OU-9 Ecological Assessment performed this walkover. Since the ecologist was very familiar with the site, the focus of the March 2000 field effort was to re-examine the habitats which had been mapped and characterized during the OU-9 Ecological Assessment, and determine what, if any, changes had occurred in the intervening time period. Another goal of the March 2000 examination was to determine if the site now possessed habitat suitable for protected species and, secondarily, if target species to be evaluated in the SLERA were present based on direct or indirect indications. During the OU-9 Ecological Assessment, no state or federally protected species were found to be permanent residents of the site and the walkover survey confirmed that this was still true.

Given that the March 2000 site visit occurred prior to the onset of the growing season, it was not possible to conduct a thorough plant inventory, nor was this the focus of the investigation. It was possible to collect only general plant community information and map habitat boundaries to determine the percent coverage of each habitat type.

On Parcel 4, a variety of habitat types occur as illustrated in Figure 2-3. These habitats and area(s) where they were found were:

1. Mesic grassland.
2. Subxeric grassland.
3. Low gradient upland forest dominated by south and west aspects.
4. Low gradient upland forest with level or nearly level topography.
5. Early successional scrub/shrub.
6. Late successional scrub/shrub.

Mesic grassland occurs only along the western site boundary, in the large field occupying the lowest elevations (i.e., 700 to 710 ft) near the Miami-Erie Canal. Mesic grasslands and subxeric grasslands superficially resemble each other, but differing moisture regimes give rise to

markedly different herbaceous communities. Whereas subxeric grasslands are located on topographic uplands, mesic grasslands are positioned on the more moist and fertile Ross soils of the Great Miami River's historic floodplain (Davis et al., 1976). In 1992, a total of 49 plant species were documented in mesic grasslands on Parcel 4 during fixed-area plot sampling (DOE 1994). Early season dominants included common brome grass, Japanese brome grass, meadow fescue, and Kentucky blue grass. During the March 2000 walkover, mesic grassland was found to occupy approximately 6.92 acres of Parcel 4.

On Parcel 4, subxeric grassland is found in more elevated positions than mesic grassland, in areas between 720 and 850-ft elevation (formerly upland pastures). Because of their upland topographic position they are well drained and seasonally droughty. On the west-facing slope near the eastern site boundary, a series of tile drains (presumably emplaced by the former landowner) enhance drainage. In some areas routine mowing is still conducted by Mound Plant personnel. In these areas, the vegetative community is largely herbaceous. However, since 1992, much of the subxeric grassland on Parcel 4 has not been maintained and is rapidly converting to an early successional scrub/shrub community. Shrub and tree seedlings are common in the unmaintained areas, and most will likely convert to an early successional scrub/shrub community within a few years. In 1992, the dominant herbaceous species in the subxeric grassland were meadow fescue, Kentucky blue grass, Canada blue grass, and rough dropseed. Canada goldenrod, spotted knapweed, Queen Anne's lace, and English plantain were also common. In the present investigation, teasel was one of the more common herbaceous elements in unmaintained areas. Subxeric grassland presently occupies approximately 40.12 acres of Parcel 4.

Low gradient upland forest dominated by south and west aspects occurs on the northern and eastern areas of Parcel 4. The boundaries of this community have changed little since 1992, except that some of the bordering scrub/shrub communities have grown to become upland forest. Areas vegetated by upland forest have gently to moderately sloping topography; elevations range from about 750 to 860 ft. The vegetative composition is comprised primarily of relatively young, mixed deciduous species underlain with dense stands of Amur honeysuckle. Apart from several widely scattered super-dominant trees, the overstory has an even-aged appearance. This suggests that these areas were once pasture containing scattered shade trees. Many of these former shade trees are still present, but are now surrounded by developing forest. Low gradient upland forest dominated by south and west aspect covers approximately 30.25 acres of Parcel 4.

Low gradient upland forest with level or nearly level topography occurs in the southern and western areas of Parcel 4, and along Benner Branch and its various drainage pathways. The largest tracts of this habitat type occur west of the center of Parcel 4. Low gradient upland forest with level or nearly level topography is associated with the seasonal drainage pathways, and shares many vegetational characteristics with the forest community situated upgradient. This habitat type occupies approximately 11.43 acres of Parcel 4.

Early successional scrub/shrub are defined as grasslands, pastures, and other previously disturbed areas that have been abandoned for long enough periods of time to allow encroachment by shrubs and small trees (DOE 1994). There is no overstory, the middlestory is mostly open to somewhat dense, and the ground layer is covered with a moderately dense herbaceous layer. Both early and

late successional scrub/shrub communities occupy a variety of topographic positions on Parcel 4. The vegetation community consists of a mixture of herbaceous and woody species, with the herbaceous species being dominated by meadow fescue and Kentucky blue grass, and the woody species being dominated by black locust and Amur honeysuckle. All areas currently described as early successional scrub/shrub were, in 1992, characterized as subxeric grassland. In the intervening time period, routine mowing has been discontinued by Mound Plant facilities maintenance, and woody species have become established and allowed to flourish. For the purpose of this study, early successional scrub/shrub differs from late successional scrub/shrub in that the former is dominated by herbaceous species and the latter by woody species. Early successional scrub/shrub occupies approximately 5.41 acres of Parcel 4.

In general, late successional scrub/shrub communities on Parcel 4 were, in 1992, described as early successional scrub/shrub. It is expected that without further disturbance, these areas will, within a few years, succeed into upland forest habitat. Late successional shrub/scrub communities on Parcel 4 contain both herbaceous and woody plant components. However, their small trees are now beginning to form an overstory, and consequently, the herbaceous ground layer is becoming more sparse. The species composition of late successional scrub/shrub is similar to early successional scrub/shrub, but the woody species component is more advanced and thus more dominant. On Parcel 4, late successional scrub/shrub occupies approximately 5.87 acres, and is contiguous with, or nearly surrounded by upland forest communities.

2.1.4 Rare, Threatened, and Endangered Species

As part of the CERCLA Section 120 Federal Facility Agreement with the U.S. Environmental Protection Agency and the Ohio EPA, DOE conducted an ecological characterization of the Mound Plant (DOE, 1994). This work involved the identification of sensitive environments (e.g., wetlands), and seasonal studies of the following biota groups: vegetation, mammals, reptiles, amphibians, aquatic macroinvertebrates, fish, and birds. Seasonal ecological studies were initiated in June 1992 and were completed in 1994. These studies included the Miami-Erie Canal and Overflow Creek, as well as Parcel 4.

In preparation for the OU9 ecological characterization, the Ohio Department of Natural Resources-Division of Natural Areas and Preserves (ODNR-DNAP) and the U.S. Fish and Wildlife Service (USFWS) were contacted regarding rare, threatened, and endangered (RTE) species occurrences. Although information from these sources suggested a very low probability of RTE occurrence, onsite reconnaissance revealed the presence of limited specialized habitat that were believed capable of harboring protected species. During general systematic surveys of the site as part of OU9 ecological characterization study field surveys, two state-protected species were found – the dark-eyed junco (*Junco hyemalis*), a state-endangered bird; and the inland rush (*Juncus interior*), a state-endangered grass. The dark-eyed junco is a common winter visitor throughout most of the eastern U.S. and is not a permanent resident of the site. At the Mound Plant, numerous individuals were found in the fall and the winter in several areas on the North and South Properties. The inland rush was found in a seasonal grassland seepage on the South Property and is apparently a casual waif. As such, it is not expected to be a permanent part of the Mound Plant flora (DOE, 1994).

The ODNR-DNAP was also contacted in May 2000 for updated information. Within the project area, the inland rush, a state threatened plant, has been recorded in the Natural Heritage database (Appendix E). This record appears to be at the same location as found during the OU9 ecological characterization. No listed animal species were noted by the ODNR-DNAP to occur in the project area. The information provided by the ODNR-DNAP is based on information supplied by many individuals and organizations, and does not necessarily indicate that a listed species is absent from an area. There are no existing or proposed state nature preserves or scenic rivers at the project site. There are no known unique ecological sites, geologic features, breeding or non-breeding animal concentrations, champion trees, state parks, forest, or wildlife area within a one-mile radius of the project area.

The current status of the rush and the junco was not determined during the March 2000 survey since this survey was qualitative. Careful examination of all habitats on Parcel 4 revealed minor changes in certain habitat categories related to succession of the plant communities. However, no significant physical changes have occurred since completion of the Operable Unit 9 ecological characterization study. For this reason, it is assumed that permanent residents/communities of these species do not occur on or in the vicinity of Parcel 4.

The USFWS was contacted in May 2000 for updated information regarding the occurrence or possible occurrence of Federally-listed threatened or endangered species in the vicinity of the Mound Plant (Appendix E). The site lies within the range of the Indiana bat, a Federally-listed endangered species, and the eastern massasauga, a docile rattlesnake that is declining throughout its national range and may soon receive status as a Federal candidate species. The snake is currently listed as endangered by the State of Ohio. The Indiana bat and the eastern massasauga are not expected to occur on the property for the following reasons:

- During the OU9 ecological characterization, the USFWS provided a letter to the Department of Energy indicating that although the Mound Plant lies within the range of the Indiana bat, no habitat for this species was present. Consequently, bat surveys were not conducted for the Indiana bat as part of the ecological characterization. The current status of the Indiana bat was not determined during the March 2000 survey since this survey was qualitative. Careful examination of all habitats on Parcel 4 revealed minor changes in certain habitat categories related to succession of the plant communities. However, no significant physical changes have occurred since completion of the Operable Unit 9 ecological characterization study. For this reason, it is assumed that this species does not occur on or in the vicinity of Parcel 4.
- Surveys for reptiles and amphibians during the ecological characterization revealed the occurrence of several species of snakes in and along the Miami-Erie Canal and Overflow Creek and on Parcel 4 (DOE, 1994). However, the eastern massasauga was not found. In general, habitats within the 1992/1993 study area ranged from moderately impacted (e.g., recently fallow farmland on Parcel 4) to significantly impacted (e.g., Miami-Erie Canal, Overflow Creek and riparian area). Consequently, potential habitat for the massasauga was very limited and the species is not considered to occur on or in the vicinity of Parcel 4 or along the Miami Erie Canal and Overflow Creek. The current status of the eastern massasauga was not determined during the March 2000 survey since this survey was

qualitative. Careful examination of all habitats on Parcel 4 revealed minor changes in certain habitat categories related to succession of the plant communities. However, no significant physical changes have occurred since completion of the Operable Unit 9 ecological characterization study. For this reason, it is assumed that this species does not occur on or in the vicinity of Parcel 4.

2.2 Extent of Contamination

Historical operations and accidental releases from the Mound Plant have resulted in the discharge of radiological (primarily plutonium and tritium) and non-radiological contamination onto the Mound Plant site, the Plant Drainage Ditch, and the off-site Miami-Erie Canal. There were no known direct releases of site contaminants to Parcel 4, though there is the potential for past on-site releases to migrate onto the property primarily through surface water runoff. Several characterization investigations have been conducted on Parcel 4 to determine the extent of contaminant migration to this adjacent property. PRS 306, PRS 314, and PRS 406 are located in Parcel 4. PRS 306 is a groundwater seep; PRS 314 is an area that contained farm trash and potentially oil from previous farm operations; and PRS 406 is at the northern end of Parcel 4 and may contain radiological contamination. The New Property Risk Assessment concluded that no further assessment was needed for PRS 306, PRS 314, and PRS 406 (DOE, 1996a).

All Parcel 4 data used in this evaluation were obtained from the reports listed in Table 2-1 and all data were collected and analyzed according to the Data Quality Objectives specific to each individual project. Samples were collected throughout the site as shown in Figure 2-4. The data used in support of this evaluation are provided in Appendix A. Media investigated during these studies included surface and subsurface soil, surface water and sediment from Benner Branch, and groundwater. Samples were analyzed for radionuclides, VOCs, SVOCs, pesticides/PCBs, inorganics, and anions. No remediation has occurred on Parcel 4.

2.3 Contamination and Transport

The primary source of contamination at Parcel 4 consists of residual soil contaminants as a result of runoff from the adjacent plant. Radionuclide and chemical contaminants at this site can be transported to other media through atmospheric deposition, via surface water movement, erosion, and through leaching to groundwater. In the atmosphere, radon (and daughters) released from impacted soils, along with other radioactively and chemically contaminated dusts, can be suspended in the air by wind movement and be transported off-site. The contaminated particles can be deposited on surfaces at considerable distances from the site.

Movement of surface water over contaminated soils or sediments can provide a means for transport of contaminated materials. Infiltration of surface water can transport contaminated material in the soil into groundwater. Movement of contamination by surface water runoff during storms and/or erosion processes is suspected in Parcel 4 because site-related contaminants have been measured at some locations in the soil in Parcel 4.

Contaminants may also be transferred through the food chain. Plants and soil-dwelling organisms can take up contaminants from surface and subsurface soil, and certain contaminants may biomagnify up the food chain. Aquatic organisms can bioconcentrate contaminants from surrounding surface water and/or sediment environments.

2.4 Potential Receptors

A field investigation (site walkthrough) in support of the ecological risk assessment of Parcel 4 was performed 21 and 22 March 2000. The primary goal of the field investigation was to gather information on changes in general habitat cover since the 1992/1993 OU 9 Ecological

Investigation, and to assess the potential for occurrence of several receptor species for evaluation in the SLERA. To that end, the field investigators examined Parcel 4 for plants, fish, and/or wildlife that may be potentially exposed to contaminants of concern. Target species were selected for an effect assessment based on several criteria including, but not limited to, recreational importance, sensitivity to ecological change, sensitivity to contaminants, and importance to the well being of protected and recreationally important species.

At the time the field investigation was conducted, the Mound Plant and vicinity were experiencing typical early spring weather. Daytime temperatures ranged from 40 to 60° F. There had been recent rainfall and nearly all intermittent stream channels carried surface flow. Leaves were starting to appear on woody vegetation, and some early spring flowers were in bloom. Results from the on-site examination were supplemented with sampling data presented in Operable Unit 9, Ecological Characterization Report (DOE 1994). This report, summarizing multi-seasonal studies conducted between spring 1992 and fall 1993, provides detailed, quantitative and qualitative data on several biota groups, including plants, birds, small and large mammals, herptiles (reptiles and amphibians), fish, and aquatic macroinvertebrates. Careful examination of all habitats on Parcel 4 by the WESTON ecologist who directed the OU9 ecological characterization study revealed minor changes in certain habitat categories related to succession of the plant communities. However, no significant physical changes have occurred since completion of the Operable Unit 9 ecological characterization study. For this reason, it is assumed that most animal species inventoried in 1992 and 1993 are still present at roughly the same abundance. The reader is referred to Operable Unit 9, Ecological Characterization Report (DOE 1994) for a listing of the species found to inhabit Parcel 4.

2.4.1 Target Terrestrial Receptors

Exposure of terrestrial wildlife (i.e., mammals, birds, amphibians, and reptiles) to constituents of potential concern (COPCs) occurs primarily when animals feed in areas impacted by site contamination. Plants are the major biotic component of the terrestrial environment and serve as the major source of food and shelter for other living forms within the terrestrial ecosystem. Earthworms and other soil-dwelling organisms also serve as a major food source for other living organisms. These organisms are directly exposed to contaminants in their soil environment, and earthworms directly ingest soil. In this screening-level evaluation, several target terrestrial receptors from several trophic levels (i.e., herbivores and insectivores) were selected to represent animal populations that inhabit the site and the surrounding areas (Table 2-2). The selected target species have been observed on Parcel 4 during all sampling seasons, represent several feeding guilds, and are commonly used as receptors of concern in ecological risk assessments. Exposure to surface water and sediment in Benner Branch by aquatic wildlife species (e.g., muskrats, mallards, great blue heron, and mink) was not evaluated due to the intermittent nature of this surface water feature and because no fish were found during the ecological characterization study (DOE, 1994). A lack of intake and toxicological data for reptiles and amphibians is the reason impacts of chemical contamination cannot be quantified for these organisms. State/federally listed species were not selected as target endpoint species because they are not permanent residents, the habitat to support these species is not present at the site, and the lack of intake and toxicological data to quantify risks to these species.

**Table 2-2 Receptors of Concern
Parcel 4, Mound Plant
Montgomery County, Ohio**

Terrestrial Habitat
Plants
Soil-dwelling organisms
Birds
Herbivore (i.e., northern cardinal)
Insectivores (i.e., American robin)
Mammals
Herbivore (i.e., meadow vole; white-tailed deer)
Insectivore (i.e., short-tailed shrew)
Reptiles/Amphibians
Aquatic Habitat
Fish and other aquatic organisms
Benthic invertebrates

Plants

Plants are the major biotic component of the terrestrial environment and serve as the major source of food and shelter for other living forms within the terrestrial ecosystem. Because abundance and composition of plants in a terrestrial ecosystem are integral to the overall health of the system, it is essential that the assessment of ecological risks to terrestrial communities include an evaluation of the effects that environmental stressors may have on the growth and survival of vascular plants within the ecosystem (Fletcher et al., 1990).

Soil-dwelling Organisms

Earthworms and other soil-dwelling organism serve as a major food source for other living organisms. An earthworm's feeding and burrowing activities break down organic matter and release nutrients, and improve aeration, drainage, and aggregation of soil (Efroymsen et al., 1997a). These organisms are directly exposed to contaminants in their soil environment, and earthworms directly ingest soil.

Meadow vole

Meadow voles (*Microtus pennsylvanicus*) are small rodents (172 to 259 mm in length) that usually have long, soft fur that is dull chestnut-brown above, and silvery-gray below. The ears are small, as are the eyes, and the tail is short (32 to 63 mm). Meadow voles inhabit low moist areas or high grasslands with rank growths of vegetation and also occur near streams, lakes, and open swamps. They forage both during the day and at night, and feed on a variety of green plants, including both monocots and dicots. They also eat some insects, though not to the extent that *Peromyscus* (mice) do. The meadow vole occurs throughout most of northern North

America, including all of Ohio. It is a prolific species, capable of rapid population increase under favorable conditions. With their high reproductive potential and their colonizing ability, they can adapt well to frequent changes in agricultural land use. At the Mound Plant, a single meadow vole was captured in 1992 in a live trap set on the lower slope of the Main Hill. Since 1992/1993, much of Parcel 4 has not been maintained, and grassy areas formerly mown on a routine basis by the Mound Plant maintenance staff now are covered with rank growths of herbaceous vegetation or have progressed into an early successional scrub/shrub community. The meadow vole was selected as a receptor species to represent mammalian herbivores because there presently exists on Parcel 4 much suitable habitat and the species is expected to be one of the more common herbaceous mammals in the study area.

Short-tailed shrew

The short-tailed shrew (*Blarina brevicauda*) is a small insectivore, 93 to 134 mm in length. It is dark gray to black with a pointed nose, tiny eyes, and concealed ears. As the name suggests, the tail is very short (19 to 30 mm). The only other species of shrew in the vicinity of the Mound Plant that has a short tail is *Cryptotus parva*, the least shrew. The short-tailed shrew is primarily nocturnal, but occasionally is active during the day. It prefers moist forests, but is found in brushy areas, along fencerows, and in pastures throughout the eastern United States. Like other shrews, *Blarina* is primarily a meat eater. Its diet includes other small mammals such as meadow voles and deer mice as well as invertebrates, such as grasshoppers and crickets. In 1992, short-tailed shrews were collected at the Mound Plant from a seepage area at the base of the southern slope of the Main Hill, and in the scrub/shrub vegetation community near the crest of the SM/PP Hill. Greater areas covered by scrub/shrub and tall grass now exist on Parcel 4 because no routine mowing of the large open areas is performed by Mound Plant maintenance. Thus, the short tailed shrew was selected as a receptor species to represent mammalian insectivores because there presumably is abundant food source and habitat for short-tailed shrews, and thus greater numbers of this small predator on Parcel 4 are expected.

White-tailed deer

The white-tailed deer (*Odocoileus virginianus*) is the most common large deer in eastern North America and is characterized by its teeth, which lack upper incisors, and its hooves. The antlers of males consist of a main beam with prongs. White-tailed deer measure 1600 to 2150 mm in length and are reddish-tan in summer and bluish-gray in winter. The tail is long (255 to 360 mm) and is white on the underside. White-tailed deer are found throughout most of North America and may occupy forested, brushy, and open areas. Their diet consists mostly of browse in winter, but grasses, forbs, fruits, and foliage of shrubs and small trees are eaten in summer.

During the ecological assessment for Operable Unit 9 (DOE 1994), conducted in 1992 and 1993, one or more white-tailed deer were observed on Parcel 4 on 17 separate occasions. The precise size of the deer herd occurring on Parcel 4 was not determined, but appeared to vary. On two separate occasions, seven (7) deer were seen in a single herd. Both male and female deer were seen during the Operable Unit 9 ecological characterization. On 21 and 22 March 2000,

numerous scat, bedding areas, and other indications of white-tailed deer occurrence were found on Parcel 4. Thus the white-tailed deer was selected as a large mammal herbivorous receptor of concern because it appears that they are still relatively common at Mound Plant.

American Robin

The American robin (*Turdus migratorius*) is one of North America's most recognizable birds. Standing from 9 to 10 ½ inches tall, the top and sides of the head are black, and the underparts are mouse gray or deep mouse gray. The tail is dark, and tipped with white, and the throat is white, and streaked with black. The chest, breast, upper abdomen, sides, flanks, and under wing-coverts are plain, deep cinnamon-rufous in color. The robin is considered a habitat generalist, being found in woodlands, gardens, and parks. The northern robin's distribution includes all of eastern and northern North America, and it is a year-round resident in Ohio. It nests on buildings, and any structures offering sufficient support, including trees and shrubs. The diet includes earthworms, snails, and other invertebrates, and much fruit. The young are fed insects.

In the Ornithological Committee of Dayton Audubon Society's publication on Birds of Dayton, robins are described as being a common migrant and summer resident, and an uncommon to rare species in winter. In 1992, it was found at the Mound Plant site during all sampling periods of the Operable Unit 9 ecological characterization study, and it was confirmed nesting in several areas of the Main Hill and South Property. The Amur honeysuckle thickets on the SM/PP Hill were found to provide refuge during the winter for large numbers (several hundred) of robins. On 21 and 22 March 2000, numerous robins were found on Parcel 4 in a variety of habitats, including early and late successional scrub/shrub, mesic and subxeric grassland, and low gradient upland forest. A robin was selected as an avian receptor species to represent insectivorous birds because of its feeding habits and its year-round residency.

Northern Cardinal

The northern cardinal (*Cardinalis cardinalis*) is 7.5 to 9 inches long, and has a wingspread of 10 to 12 inches. The head has a prominent crest, and in the male, the head and underparts are deep vermilion red. The chin and a mask around the base of the bill are black, and the back is washed with olive-gray. The tail is brick red. The female's upperparts are pale olive-brown, and her underparts are tawny-olive, shading to pinkish buff on the lower belly. The cardinal's range includes eastern North America from southeastern South Dakota, southern Iowa, northern Indiana, southern Ontario, and southern New York south to southern Georgia and western Florida. The cardinal is an abundant species within its range, and is a generalist in its habitat preference, inhabiting thickets, dense shrubs, undergrowth, residential areas, and riparian thickets. Adults feed primarily on vegetable matter (i.e., seeds and wild fruit). Insects comprise a minor portion of their diet. In Parcel 4, during the Operable Unit 9 ecological characterization, the cardinal was found in all seasons wherever there was dense cover. A cardinal was selected as an avian receptor species to represent herbivorous birds because of its feeding habits and its year-round residency.

2.4.2 Target Aquatic Receptors

Aquatic invertebrates were selected as receptors because of their close association with a benthic (i.e., sediment) environment. Aquatic organisms (e.g., fish, aquatic plants, and aquatic insects) were selected as receptors inhabiting a surface water environment. In this screening-level evaluation, the target aquatic receptors are those plant and animal populations inhabiting Benner Branch. It should be noted that no fish were found in Benner Branch during the OU9 ecological characterization study (DOE, 1994). However, fish are considered as a receptor species because vertebrates are more radiosensitive than invertebrates (BJC, 1998).

2.5 Complete Exposure Pathways

For an exposure pathway to be complete, a contaminant must be able to travel from the source to ecological receptors and to be taken up by the receptors via one or more exposure routes (EPA, 1998). For terrestrial animals, there are three basic chemical exposure routes: ingestion, inhalation, and dermal absorption. Little information is available for quantifying the inhalation or dermal absorption exposure pathways for terrestrial animals. Although these exposure pathways may be complete, the risk is considered minimal when compared to ingestion. For terrestrial plants, root absorption of contaminants in soil or leaf absorption of contaminants evaporating from the soil are potential exposure routes. For soil-dwelling organisms, direct contact with the dermis and ingestion of contaminated soil are the primary exposure routes. For aquatic organisms, direct contact with water or sediment with the gills or dermis and ingestion of water, food, and sediments are the primary exposure routes. For all ecological receptors, there is also the potential for direct gamma radiation resulting from the radioactive decay of plutonium-238 and the other radionuclide COPCs. For radionuclides, internal exposure (via ingestion and inhalation) and external exposures are the primary exposure routes for ecological receptors.

2.6 General Assessment Endpoints

Assessment endpoints are "explicit expressions of the environmental value that is to be protected" (EPA, 1998). The ecological resources selected to represent management goals for environmental protection are reflected in the assessment endpoint. Assessment endpoints link the risk assessment to management concerns and they are central to conceptual model development (EPA, 1998). The following principal criteria are used when selecting assessment endpoints (EPA, 1998):

- The contaminants present and their concentrations.
- Mechanisms of toxicity of the contaminants to different groups of organisms.
- Ecologically relevant receptor groups that are potentially sensitive or highly exposed to the contaminant and attributes of their natural history.
- Potentially complete exposure pathways.

The preliminary assessment endpoints for Parcel 4 are presented in Table 2-3. Protection of individual threatened and endangered species was not considered as an assessment endpoint because no listed species are expected to permanently occur on or in the vicinity of Parcel 4.

Table 2-3

**Preliminary Assessment Endpoints
Parcel 4, Mound Plant, Montgomery County, Ohio**

Preliminary Assessment Endpoint
<i>Parcel 4</i>
Changes in plant and soil-dwelling organism communities attributable to COPCs measured in soil.
Potential reduction of mammal and avian populations resulting from chronic exposure to COPCs in soil.
COPC bioaccumulation and biomagnification in flora and fauna associated with potential adverse effects.
<i>Benner Branch</i>
Changes in aquatic community (i.e., fish and benthic invertebrates) structure and function attributable to COPCs measured in surface water and sediment in Brenner Branch, and groundwater discharging to surface water.

Locations where the wildlife preliminary remediation goal (PRG) is exceeded are included in Appendix F.

2.7 Conceptual Model

The conceptual model establishes the complete exposure pathways that are evaluated in the ecological risk assessment and the relationship of the measurement endpoints to the assessment endpoints (EPA, 1997). The conceptual model for Parcel 4 is presented in Table 2-4. The ecological conceptual model presents the feeding guilds supported by the existing habitat at the site. However, not all feeding guilds will be equally evaluated in the risk assessment. In most cases, a lack of intake and toxicological data for many wildlife species (e.g., reptiles and amphibians) is the reason impacts of chemical contamination cannot be quantified for these organisms. While bird and mammal species at the top of the food chain have the potential to be exposed to contaminants that have biomagnified, these carnivores tend to have large home ranges. Thus, an evaluation of potential impacts to herbivorous and insectivorous birds and mammals is expected to be more conservative since these groups would consume larger amounts of contaminated prey. Herbivores and insectivores who feed exclusively on plants or insects are expected to have a greater degree of exposure to contaminants than an omnivore who consumes a variety of prey. Thus, if risk to herbivores and insectivores is acceptable, risk to an omnivore is expected to be acceptable. Terrestrial wildlife exposure to seep water was not evaluated due to the limited potential for exposure to this medium. The seeps are seasonal features. While wildlife may ingest seep water, this water is not expected to be their sole water source as many small animals obtain water from various sources including their food, dew, etc. All feeding guilds and exposure routes that are not quantified in the risk assessment will be discussed in the uncertainty analysis.

Based on the conceptual site model, the following exposure scenarios, which are based on the presence of adequate habitat for the selected receptor species, were included in the environmental evaluation of the site:

Table 2-4

**Preliminary Ecological Conceptual Site Model
Parcel 4, Mound Plant, Montgomery County, Ohio**

Exposure Medium	Exposure Route	Plants	Soil-dwelling Organisms	Birds	Mammals	Reptiles / Amphibians	Fish	Macrobenthos
Soil <i>Parcel 4</i>	Ingestion	O	X	X	X	Δ	--	--
	Dermal contact	O	X	O	O	Δ	--	--
	Inhalation	O	X	O	O	Δ	--	--
	External	X	X	X	X	Δ	--	--
	Food/Prey	O		X	X	Δ	--	--
Sediment <i>Benner Branch</i>	Growth medium	X	--	--	--	--	--	--
	Ingestion	O	O	O	O	Δ	X	X
	Dermal contact	O	O	O	O	Δ	X	X

	Food/Prey	O	O	O	O	Δ	X	X
Groundwater/ Seeps <i>Discharge to surface water</i>	Ingestion	O	O	O	O	Δ	X	X
	Dermal contact	O	O	O	O	Δ	X	X
	External	O	O	O	O	Δ	X	X
	Inhalation	O	O	O	O	Δ	X	X
	Food/Prey	O	O	O	O	Δ	X	X

X = Potential exposure route determined to be significant for this receptor.
O = Potential exposure route determined to be insignificant for this receptor.
Δ = Potential exposure route cannot be quantified due to lack of exposure and toxicity data.
-- = Potential exposure route not of concern for this receptor.

2.7.1 *Terrestrial Habitat*

- Plant and soil-dwelling organism hazard quotient (HQ) evaluation of direct exposure to chemical and radiological COPCs in soil where media concentrations are compared with plant and soil-dwelling organism benchmarks.
- A primary consumer (herbivore) hazard quotient evaluation for avian and mammalian species, where cumulative internal (i.e., consumption of vegetation, incidental ingestion of soil and surface water, inhalation of dust (radiological only)) and external exposure is compared with published or derived toxicity reference values.
- A secondary consumer (insectivore) hazard quotient evaluation for an avian and mammalian species, where cumulative internal (i.e., consumption of insects/earthworms, incidental ingestion of soil and surface water, inhalation of dust (radiological only)) and external exposure is compared with published or derived toxicity reference values.

2.7.2 *Aquatic Habitat*

- Aquatic community hazard quotient evaluation for aquatic insects, aquatic plants, and benthic organisms that are directly exposed to chemical and radiological COPCs in Benner Branch surface water and sediment, and groundwater discharging to surface water where media concentrations are compared with surface water and sediment quality benchmarks.

3.0 SCREENING-LEVEL ECOLOGICAL EFFECTS EVALUATION

The screening-level ecological effects evaluation focuses on developing toxicity reference values (TRVs), listed in Appendix C for COPCs, as well as determining the complete exposure pathways that exist at the site (EPA 1996).

3.1 *Constituents of Potential Concern*

Radionuclides in soil, surface water, and sediment above site-specific background levels are considered to be radiological COPCs. To determine chemical COPCs in soil and sediment, the maximum detected concentration of a contaminant was compared to U.S. EPA Region V Ecological Data Quality Levels (EDQLs) (EPA 1999a) and site-specific background levels. To determine chemical COPCs in surface water, the maximum detected concentration of a contaminant was compared to OEPA outside mixing zone average water quality standards. If a state surface water standard was not available, the lower of Region V surface water EDQLs and federal water quality criteria were used for screening. The results of the screening are provided in Appendix B. Ecological receptors are not expected to be exposed to soil deeper than about 2 feet below ground surface (bgs); thus, soils collected below this depth were not evaluated in the SLERA.

3.1.1 *Toxicological Profiles*

Radionuclides

Ionizing radiation exists as background radiation from terrestrial sources, building materials, food, and cosmic sources. Acute doses of ionizing radiation at high levels are known to produce biological effects ranging from chromosomal changes to cell death. Radionuclides naturally decay causing a decrease in their activities or concentrations. Each radionuclide has a half-life that is a measure of how long it will take for half of the radioactive isotope to decay. The decay series of concern are summarized below and all decay products are listed in Table D-1.

Thorium-228 (Th-228)

Thorium-228 is a naturally occurring isotope, with a half-life of 1.93 years, as a member of the Thorium-232 series. Th-228 emits an alpha particle and decays into Radium-224. Th-228 also emits gamma rays following 2% of all disintegrations. Th-228 will have the same metabolic properties as Th-230 including biological half-life and target organs.

Thorium-230 (Th-230)

Thorium-230 is a naturally occurring isotope, with a half-life of 7.54×10^4 years, as a member of the Uranium-238 series. The average amount of Th-230 in the body is 3 pCi from natural sources. Th-230 emits an alpha particle and decays into Radium-226. Radium-226 has a half-life of 8×10^4 years with a biological half-life of 8×10^3 days in bone and 700 days for all other

organs. Seventy percent of thorium when taken in the body will deposit in the bone, while 4% deposits in the liver and 16% in all remaining organs.

Thorium-232 (Th-232)

Thorium-232 is also naturally occurring, with a half-life of 1.40×10^{10} years, and is the start of the Thorium series. The average amount of Th-232 intake from natural sources is 5×10^{-7} g/day with a total amount in the body of 1.4 pCi. Th-232 emits an alpha particle and decays into Radium-228, which has a half-life of 1.41×10^{10} years. Th-232 will have the same metabolic properties as Th-230 including biological half-life and target organs.

Uranium-234 (U-234)

Uranium-234 is naturally occurring, with a half-life of 2.46×10^5 years, as a member of the Uranium series. U-234 emits an alpha particle and is the precursor of Th-230. U-234 will have the same metabolic properties as Uranium-235 including biological half-life and target organs.

Uranium-235 (U-235)

Uranium-235 is naturally occurring, with a half-life of 7.04×10^8 years, and is the start of the Actinium series. The average amount of U-235 intake from natural sources is 1.9×10^{-6} g/day with a total amount in the body of 9×10^{-6} g natural uranium. U-235 emits an alpha particle and decays into Thorium-231. U-235 has a biological half-life of 8×10^3 days in the kidney and two components of biological half-life in the skeleton of 20 and 5000 days. Chemical effects to the kidney are likely to be more important than radiation effects to the body. Radiation effects to the kidneys and lungs must be considered if the uranium is enriched (higher percentage of U-235).

Uranium-238 (U-238)

Uranium-238 is naturally occurring, with a half-life of 4.51×10^9 years, and is the start of the Uranium series. U-238 emits an alpha particle and decays into Th-234. U-238 will have the same metabolic properties as U-235 including biological half-life and target organs.

Plutonium-238 (Pu-238)

Plutonium-238, with a half-life of 87.7 years, emits an alpha particle and decays into Uranium-234. Pu-238 has a 100 year biological half-life in bone and 40 years in the liver. When plutonium is taken into the body, 45% will deposit in bone, mostly on endosteal surfaces, and 45% will deposit in the liver.

Metals

Aluminum occurs naturally and makes up approximately 8% of the surface of the earth. Aluminum enters environmental media naturally through the weathering of rocks and minerals. Anthropogenic releases are primarily associated with industrial process, such as smelting. In general, decrease in pH results in an increase in mobility for monomeric forms of aluminum. In groundwater or surface water systems, equilibrium with a solid phase of form is established that

largely controls the extent of aluminum dissolution that can occur. Aluminum is not bioconcentrated in plants and it is not expected to biomagnify in the terrestrial food chain. Bioconcentration in fish is a function of the water quality, with slightly more accumulation noted at lower pH (ATSDR, 1990).

Antimony is naturally present in the earth's crust. Anthropogenic sources include metal smelting, coal-fired power plants, and refuse incineration. Antimony does not appear to appreciably bioconcentrate in fish and aquatic organisms. Uptake from soil is minor, and is correlated with the amount of available antimony. Antimony bioconcentration has been measured in small mammals, though biomagnification from lower to higher trophic levels in the food chain has not been suggested (ATSDR, 1990).

Arsenic is a relatively common element. In general, inorganic arsenic is more toxic than organic compounds, and trivalent species are more toxic than pentavalent species (Eisler, 1988). Episodes of arsenic poisoning are either acute or subacute; cases of chronic arsenosis are rarely encountered (Eisler, 1988). Arsenic is a teratogen and carcinogen that can traverse placental barriers and produce fetal death and malformations in many species of mammals (Eisler, 1988). Arsenic is bioconcentrated by organisms, but it is not biomagnified in the food chain (Eisler, 1988).

Aquatic and terrestrial organisms bioaccumulate **cadmium** at all levels of the food chain (Eisler, 1985). Mammals are less susceptible to the acute toxic effects of cadmium than aquatic insects and fish. Sublethal effects in birds and other species include growth retardation, anemia, and testicular damage (Eisler, 1985). Teratogenic effects on animals appears to be greater for cadmium than for other metals (Eisler, 1985). Cadmium does not biomagnify.

Toxic effects of **chromium** are primarily expressed at lower trophic levels (Eisler, 1986). Under laboratory conditions, chromium is mutagenic, carcinogenic, and teratogenic (Eisler, 1986). Potential endpoints include growth reductions and impaired survival (Eisler, 1986). Trivalent chromium is generally less toxic than hexavalent chromium (Eisler, 1986). In animals, hexavalent chromium is readily converted to trivalent chromium (Eisler, 1986). For aquatic life, younger life stages are more sensitive than older organisms. Chromium does not biomagnify.

Lithium is widely distributed throughout the earth's crust, though the lithium content in soil is controlled more by conditions of soil formation than by its initial content in parent rocks. Soluble lithium in soils is readily available to plants. While lithium is not known to be an essential plant nutrient, it can affect plant growth and development (Kabata-Pendias and Pendias, 1992).

Elemental **mercury** has no known normal metabolic function (Eisler, 1987). Mercury is a mutagen, teratogen, and carcinogen, and causes embryocidal, cytochemical, and histopathological effects (Eisler, 1987). Methylmercury can be bioconcentrated and biomagnified through food chains (Eisler, 1987). For all organisms, early developmental stages are the most sensitive, and organomercury compounds are more toxic than inorganic forms (Eisler, 1987).

Silver is one of the basic elements that make up the earth. Because silver is an element, it does not break down, but it can change form by combining with other substances. Silver and its compounds are not known to be mutagenic, teratogenic, or carcinogenic. Silver, as ionic Ag^+ is one of the most toxic metals known to aquatic organisms. Sorption is the dominant process that controls silver partitioning in water and its movement in soils and sediment (Eisler, 1996).

Vanadium enters the environment from both natural and anthropogenic sources. Some marine organisms bioconcentrate very efficiently. In general marine plants and invertebrates contain higher levels of vanadium than terrestrial plants and animals. Vanadium does not appear to concentrate in the aboveground portion of plants. While no data are available regarding biomagnification of vanadium, studies suggest that this is unlikely (ATSDR, 1990).

3.2 Development of Toxicity Reference Values

For each COPC with a potentially complete exposure pathway, a screening-level toxicity reference value (TRV) was developed from a review of literature. TRVs based on dose are used for bird and mammal receptors and TRVs based on media concentrations are used for fish and benthic organisms.

3.2.1 Dose-based TRVs

Chemicals

For chemicals, toxicity reference values based on no-observed-adverse-effect-levels (NOAELs) were developed for each receptor class (i.e., birds and mammals). NOAEL-based TRVs represent values believed to be nonhazardous for the listed wildlife species, and is the lowest exposure level shown not to produce adverse effects in a potential receptor. Most dose-based toxicity data were obtained from EPA (1999) and Sample et al. (1996). If a TRV was not directly available from toxicity studies, a TRV was extrapolated from available studies following methods recommended by EPA (1999). TRVs could not be developed for all chemicals; those with no available toxicity data are discussed in the Uncertainty Analysis (Subsection 5.3).

If a chronic NOAEL was not available for a constituent, uncertainty factors were used to adjust the available toxicity data to a chronic NOAEL. A factor of 10 was used to adjust from a lowest observable adverse effect level (LOAEL) to a NOAEL, and to adjust from an acute to chronic value (EPA, 1999). Studies have found that the ratio of an LD_{50} to a chronic NOAEL typically ranges from 10 to 10,000 (Sample et al., 1996). An uncertainty factor of 100 was used to adjust an LD_{50} to a chronic NOAEL (EPA, 1999b). To account for differences between test species and the receptor species, a body-weight scaling factor was used, following methodology developed in Sample et al. (1996). A scaling factor of 1 is assumed for avian species and species-specific scaling factors for mammals are presented in Appendix B. The dose-based TRVs for the receptors of concern are also presented in Appendix B.

Radionuclides

For radionuclides, the International Atomic Energy Agency (IAEA) recommends limiting the dose for terrestrial organisms to 100 mrad/day (IAEA, 1992; Sample et al., 1997). This dose limit is based on studies evaluating reproductive success and survival. A dose rate of 1 rad/day is generally considered protective of plant and invertebrate populations (IAEA, 1992; Barnhouse, 1995; Sample et al., 1997). This dose limit is based on studies of productivity and community characteristics. Invertebrates tend to be less radiosensitive than plants or vertebrates, and indirect responses to radiation-induced vegetation changes (e.g., habitat alteration) appear to be more critical than direct effects (e.g., mortality) from radiation (IAEA, 1992; Sample et al., 1997). The recommended acceptable dose rate to natural populations of aquatic biota is 1 rad/day based on results of the reviews summarized in NCRP Report No. 109 (NCRP 1991; BJC, 1998). This limit was intended to apply to the most radiosensitive populations of aquatic organisms (BJC, 1998).

3.2.2 Media-based TRVs

Chemicals

Soil

Toxicity data for plants and soil-dwelling organisms have been developed for a limited number of organic and inorganic chemicals. EPA recently released draft Ecological Soil Screening Levels (EPA, 2000) for plants, invertebrates, birds, and mammals. Screening benchmarks for evaluating chemical effects on terrestrial plants and soil- and litter-dwelling invertebrates have been developed by ORNL (Efroymsen et al., 1997a&b).

Surface Water

As a means of characterizing aquatic toxicity, ambient water quality criteria (AWQC) have been developed for the protection of 95 percent of all aquatic life where sufficient data are available (EPA, 1992). Not only fish, but also aquatic invertebrates and plants are protected (EPA, 1986). The Ohio EPA has established water quality standards to protect aquatic life habitat (Ohio Administrative Code, Chapter 3745-1). For metals, most water quality criteria are hardness-dependent. Surface water data were used to calculate hardness values and hardness-dependent criteria for each water body (Appendix B, Table B-5). A hardness value of 400 mg/L was used for groundwater.

Sediment

Various agencies (CCME, 1999; Long et al., 1995; Jones et al., 1996) have developed sediment quality criteria and benchmarks for the assessment of toxicological effects on sediment-associated biota. Note that these benchmarks are not remediation goals; remediation goals must consider the adverse effects on habitat and remobilization of contaminants caused by removal or remediation of sediments (Jones et al., 1996). The sediment benchmarks should not be considered as the sole measure of sediment toxicity; rather, field studies and toxicity tests are

primary indicators of sediment toxicity (Jones et al., 1996). The sediment benchmarks provide a means to determine which chemicals are most likely causing toxicity as presented in Jones et al. (1996). "The use of multiple benchmarks also provides an indication of the likelihood and nature of effects. For example, exceedance of only one conservatively estimated benchmark may provide weak evidence of real effects, whereas exceedance of multiple benchmarks of varying conservatism may provide strong evidence of real effects." (Jones et al., 1996).

The Canadian Council of Ministers of the Environment (Smith et al., 1996; CCME, 1999) has developed environmental quality guidelines that include sediment quality guidelines for the protection of aquatic life. The guidelines include a threshold effect level (TEL), which represents the concentration below which adverse effects were expected to rarely occur, and the probable effect level (PEL), which is defined as the level above which adverse effects were expected to occur frequently. The TEL is also generally recommended as the interim freshwater sediment quality guideline (ISQG). Concentrations that fall between the range of TEL and PEL are occasionally expected to be associated with adverse biological effects.

The National Oceanic and Atmospheric Administration (NOAA) has developed sediment effect ranges to determine concentrations of chemicals which are likely to result in effects based upon available sediment data collected primarily in marine and estuarine environments throughout the United States (Long et al., 1995). The Effects Range-Low (ER-L) values represent the lower tenth percentile of the range of concentrations in which effects were observed or predicted. The Effects Range-Median (ER-M) values represent median concentrations.

Radionuclides

Using methods presented in Blaylock et al. (1993), the Bechtel Jacobs Company (BJC) (1998) has developed benchmarks for radionuclides in sediment and surface water that result in a total dose rate of 1 rad/day for fish. Two types of benchmarks were derived: single-media benchmarks and multimedia benchmarks. The benchmarks include exposures from parent isotopes and all short-lived daughter products. They also include exposures from all major alpha, beta, and gamma emissions for each isotope. The single-media benchmarks are based on exposures to radionuclides in one medium but not the other. The water benchmarks include internal and external exposures from water only. The sediment benchmarks include only external exposures from sediment. These benchmarks are intended for use when both water and sediment data are available. That is, measured sediment concentrations should be compared to the sediment values and collocated water measurements should be compared to the water values (BJC, 1998).

The multimedia benchmarks are for use when only one medium was sampled at a site. The water benchmarks account for internal exposures, external exposures to water, and external exposures to sediment. The sediment concentrations are estimated from the water concentrations using the radionuclide-specific soil-water partition coefficients (K_d). The sediment benchmarks account for external exposures to sediment plus internal exposures, which were estimated based on the radionuclide-specific transfer factors (i.e., the K_d and BCF). Both the single-media and multimedia benchmarks were also developed for two size categories of fish (BJC, 1998). Due to the

uncertainty associated with use of generic transfer factors, the single-media benchmarks are considered to be more reliable than the multimedia benchmarks (BJC, 1998). Both benchmarks are used in the SLERA to provide an indication of the likelihood and nature of effects.

4.0 SCREENING-LEVEL EXPOSURE ESTIMATE

The screening-level total effective dose equivalent (TEDE) involves the selection of exposure parameters for use in calculating a daily exposure dose or exposure concentration. Measured environmental medium concentrations (e.g., surface water, sediment, and soil) are used for estimating TEDE of terrestrial and aquatic wildlife to site contaminants.

4.1 Dose-Based Exposure

4.1.1 Radionuclide Exposure

To estimate radionuclide exposure by ecological receptors (i.e., plants, insects, small mammals/birds, small-medium mammals/birds, medium mammals/birds, and large mammals) a radiation dose rate in millirads per day (mrad/d) was calculated for each receptor group following the methodology described in *Methods and Tools for Estimation of the Exposure of Terrestrial Wildlife to Contaminants* (Sample et al., 1997). This methodology uses radionuclide exposure point concentrations in environmental media such as surface water, soil, and sediment, and radionuclide-, media-, receptor- and pathway-specific factors to calculate doses from alpha, beta, and gamma emissions and includes dose rates from all short-lived daughter products. Dose rates from each radionuclide (plus appropriate daughters) are then summed over all exposure routes and all radionuclides to calculate an estimate of the TEDE received for each receptor (Sample et al., 1997).

Exposure routes evaluated for radionuclides include external exposure through direct radiation from soil (both aboveground and below ground) and internal exposure through ingestion of soil, prey, and water and through inhalation of contaminated dust. Radionuclide exposure concentrations and doses are presented in Appendix D.

External Exposure: Direct Radiation from Soil

The equation for aboveground dose from external exposures for a plant or wildlife receptor is (Sample et al., 1997):

$$D_{abovegrd} = F_{above} \times F_{ruf} \sum C_{soil,i} \times DF_{grd,i} \times CFb \times ECF$$

Where:

- | | | |
|----------------|---|--|
| $D_{abovegrd}$ | = | external dose rate to receptor from aboveground exposures to contaminated soil aboveground (mrad/day). |
| F_{above} | = | dose rate reduction factor accounting for the fraction of time the receptor spends aboveground (unitless). |

- F_{ruf} = dose rate reduction factor accounting for ground roughness (unitless) [Representative average of 0.7 (Eckerman and Ryman 1993) is reasonable default].
- $C_{soil,i}$ = activity of radionuclide i in surface soil (pCi/g).
- $DF_{grd,i}$ = dose coefficient for radionuclide i in soil contaminated to given depth (Eckerman and Ryman 1993) (Sv/sec per Bq/min).
- CFb = conversion factor to change Sv/sec per Bq/min to mrad g/pCi day. (Equals 5.12×10^{14}).
- ECF = elevation correction factor to adjust dose coefficients to value representative of effective height of animal aboveground.

The equation for below ground external exposures of earthworms and wildlife receptors is (Sample et al., 1997):

$$D_{belowgrd} = 1.05 F_{below} \sum C_{soil,i} \times \epsilon_i \times CFa,$$

Where:

- $D_{belowgrd}$ = external dose rate to earthworm or wildlife receptor in burrow from contaminated soil (mrad/day).
- F_{below} = dose rate reduction factor accounting for the fraction of time the receptor spends below ground (unitless).
- $C_{soil,i}$ = activity of radionuclide i in surface soil (pCi/g).
- ϵ_i = energy for gamma emissions by nuclide i (MeV/nuclear disintegrations (MeV/nt),
- 1.05 = conversion factor to account for immersion in soil vs. water (estimated value; Keith Eckerman, Health Sciences Research Division, Oak Ridge National Laboratory, personal communication, June 1996).
- CFa = conversion factor to go from MeV/nt to g mrad/pCi day. (5.12×10^{-2}).

Alpha particles have low penetration ability and are not considered for external exposure. The effective dose coefficients used incorporate both high energy beta and gamma emissions (Sample et al., 1997). Below ground exposure assumes immersion in a continuous soil medium. The exposure fractions reflect the fraction of time the receptor spends above and below ground. For this analysis, values of 1 were conservatively applied for both above- and below ground exposure. In addition, all default exposure parameters presented in Sample et al. (1997) were used to estimate external exposure.

Internal Exposure: Ingestion

Wildlife receptors may receive internal radiation doses after ingesting contaminated prey, soil, or water. Internal exposure for wildlife that consume a variety of prey types, ingesting soil, and drinking water, as well as plants and invertebrates taking up contaminants directly from the soil can be estimated as (Sample et al., 1997):

$$D_{ing} = \sum QF \times C_{tissue} \times \epsilon_i \times CFa \times AF$$

Where:

- D_{ing} = internal dose rate received after ingestion of contaminated prey and soil (mrad/day).
- QF = quality factor to account for the greater biological effectiveness of α particles (20 for α ; 1 for β and γ emissions; unitless).
- C_{tissue} = activity (pCi/g) of radionuclide i in tissue of organism.
- ϵ_i = energy for α , β , or γ emissions by nuclide i (MeV/nt).
- CFa = conversion factor to go from MeV/nt to g mrad/pCi day (5.12×10^{-2}).
- AF = absorption factor (unitless).

Radionuclide activity in tissue was estimated from soil activity using uptake factors and bioaccumulation factors presented in Sample et al. (1997). Absorbed energy fractions for alpha and beta radiation were conservatively assumed to be 1 for all receptors. Beta absorption fractions may be less than one for plants and earthworms, since some fraction may have sufficient energy to pass through smaller organisms. For gamma radiation, absorption fractions presented in Sample et al. (1997) were used. In addition, all default exposure parameters presented in Sample et al. (1997) were used to estimate ingestion exposure.

Internal Exposure: Inhalation

Wildlife species that use burrows may receive an additional internal dose from inhalation of dust originating from contaminated soil, especially since they may spend a large portion of their time in below ground burrows. Intake of radionuclides by inhalation is estimated as (DOE 1995b, as cited in Sample et al., 1997):

$$D_{inh} = QF \times F_{below} \sum C_{soil,i} \times A \times AD \times \epsilon_i \times CFa \times AF$$

Where:

- D_{inh} = internal dose rate from inhalation of contaminated soil (mrad/day).

F below	=	dose reduction factor for fraction of time receptor spends below ground (unitless).
C soil, i	=	activity of radionuclide i in surface soil (pCi/g).
A	=	mass of respirable dust per volume of air breathed (0.1 g/m ³ ; DOE 1995b).
AD	=	air density (1200 g/m ³ ; Eckerman and Ryman 1993).
ε _i	=	energy for α, β, or γ emissions by nuclide i (MeV/nt).
CF _a	=	conversion factor to go from MeV/nt to mrad g/pCi/day (5.12 x 10 ⁻²).
AF	=	absorption factor (unitless).

The exposure fraction reflects the fraction of time the receptor spends above- and below ground. For this analysis, a value of 1 was conservatively applied for inhalation exposure. In addition, all default exposure parameters presented in Sample et al. (1997) were used to estimate inhalation exposure.

Chemical Exposure

To estimate chemical exposure by avian and mammalian ecological receptors, exposure doses were estimated for the selected target species using the following general equation:

$$Dose = (C_{medium} \times IR \times FI) / BW$$

Where:

Dose	=	Daily dose through exposure route, e.g., soil, surface water, prey (mg/kg-day).
IR	=	Ingestion rate of the medium (kg/day or L/day).
C _{medium}	=	Chemical concentration in soil, surface water, or prey (mg/kg or mg/L).
FI	=	Fraction ingested from contaminated source (unitless).
BW	=	Body weight (kg).

Total exposure to a receptor organism can be determined by summing the dose received by soil, food, and water. Intake of contaminants via surface water was considered only for chemical COPCs. To ensure that sites which may pose an ecological risk are properly identified, the EPA

suggests that exposure values should be consistently biased in the direction of overestimating risk. "Without this bias, a screening evaluation could not provide a defensible conclusion for an absence of ecological risk" (EPA, 1996). Conservative assumptions were used to estimate exposure levels in this assessment, including:

- Maximum COPC concentrations at exposure point.
- 100% bioavailability of contaminants.
- 100% of diet consisting of most contaminated food item.
- Minimum body weights and maximum ingestion rates.
- Most sensitive life stage.
- Home range lies entirely within site.

Birds and mammals representing several trophic levels were proposed as the target receptors for this evaluation. Exposure of terrestrial wildlife to COPCs occurs primarily when animals feed in areas impacted by site contamination. The species selected as receptors of concern represent a range of feeding relationships within Parcel 4. Receptors evaluated include herbivores and insectivores. Exposure of a piscivore was not considered because no fish have been found in Benner Branch. Exposure of a carnivore was not evaluated because none of the contaminants of concern are expected to biomagnify in the terrestrial food chain, there is a lack of bioaccumulation factors for small mammals, and the large home range of most carnivores will limit their site exposure.

The chemical concentration in food (i.e., plants and earthworms) were estimated using chemical-specific bioconcentration factors (BCFs). Chemical concentrations in plants were estimated by multiplying chemical-specific plant uptake factors (PUFs) by measured soil or sediment concentrations. Bioaccumulation factors (BAFs) were used to estimate earthworm concentrations from soil exposure.

4.2 Media-Based Exposure

4.2.1 Radionuclide Exposure

Using methods presented in Blaylock et al. (1993), Bechtel Jacobs Company (1998) has developed benchmarks for radionuclides in sediment and surface water that result in a total dose rate of 1 rad/day for fish. Two types of benchmarks were derived: single-media benchmarks and multimedia benchmarks. These benchmarks were used to estimate radionuclide exposure by aquatic life in Benner Branch and from groundwater discharge to surface water. It should be noted that no fish were found in Benner Branch during the OU9 ecological characterization study (DOE, 1994). However, fish are considered as a receptor species in development of radiological benchmarks because vertebrates are more radiosensitive than invertebrates (BJC, 1998).

4.2.2 Chemical Exposure

Chemical exposure by plants, soil-dwelling organisms, sediment-dwelling organisms, and aquatic life such as fish are evaluated in this assessment through direct comparison to ecological benchmarks rather than dose calculations. To estimate chemical exposure by plants and soil-dwelling organisms, soil concentrations are compared directly to toxicity benchmarks. To estimate chemical exposure by sediment-dwelling organisms and aquatic life, sediment and surface water concentrations are compared directly to toxicity benchmarks (e.g., sediment effects range concentrations and ambient water quality criteria).

5.0 SCREENING-LEVEL RISK CHARACTERIZATION

The screening-level risk characterization integrates information from the screening-level problem formulation, screening-level ecological effects evaluation, and the screening-level exposure estimate to predict the nature and extent of ecological risk or threat, as well as the environmental impact of previous site activities. The hazard quotient (HQ) approach is used as an indicator of the risks posed to surrogate ecological receptors from exposure to site-related contaminants (EPA, 1996). The hazard quotient compares exposure values to TRVs, and can be expressed as the ratio of a potential exposure level to the TRV:

$$\text{HQ} = \text{Exposure} / \text{TRV}$$

where:

HQ = Hazard quotient (unitless).

Exposure = Exposure concentration at the exposure point (e.g., mg-contaminant/kg-sediment or pCi/g) or estimated contaminant exposure dose at the exposure point (mg contaminant/kg body weight/day or mrad/day).

TRV = Toxicity reference value, i.e. effect dose or effect criteria (in units that match the exposure concentration). Listed in Appendix C

Exposure to the same chemical or radionuclide (plus daughters) through multiple exposure routes (e.g., soil ingestion, prey ingestion) is assumed to be cumulative. Consequently, a total hazard index (HI) for a specific COPC examines the potential risk posed by the COPC through more than one exposure route:

$$\text{HI} = \sum \text{HQ}_i$$

Where:

HI = Hazard index (unitless)

HQ_i = Hazard quotient for exposure route i (unitless)

A HQ or HI exceeding 1.0 indicates the species of interest (or the species for which the toxicity data was based on) may be at risk of an adverse effect from the particular COPC, exposure route, or medium on which the HQ (or HI) was based. Further evaluation may be needed in terms of site-specific toxicity data for a given target receptor.

For aquatic life exposure to radionuclides, the concentrations of radionuclides in water or sediment were screened against single-media and multi-media benchmarks by calculating a HQ.

The radiological benchmarks are normalized in an attempt to account for the biological effectiveness of the different types of radiation, which allows for the calculation of an HI. The HI is the measure of the total dose rate to the organism and accounts for all three exposure pathways: total internal dose, total external dose from water, and total external dose from sediment (BJC, 1998).

5.1 Risk to Terrestrial Receptors

5.1.1 Radionuclides

Terrestrial organisms may be exposed to radionuclide concentrations in soil via external exposure through direct radiation, via internal exposure through ingestion of soil and food, and via internal exposure through inhalation of contaminated dust. Maximum detected radionuclide concentrations were applied in exposure models to estimate total radionuclide exposure doses. These doses were compared to IAEA-recommended dose limits for terrestrial organisms (e.g., mammals and birds) and plant and invertebrate populations. The total hazard indices for these receptor groups are presented in Table 5-1. The HI is the sum of all exposure routes and all radionuclides (plus daughters). Due to the conservative method for estimating exposure doses, these risks may be overestimated as discussed further in the Uncertainty Analysis (Section 5.3).

For all receptors, total HIs do not exceed unity, suggesting that the radionuclides measured in Parcel 4 soil pose a negligible risk to terrestrial biota.

5.1.2 Chemicals

Plants

Plants may be directly exposed to chemical COPCs in soil. There is a potential for adverse effects to plants from exposure to aluminum, antimony, chromium, lithium, silver, and vanadium (Table 5-2).

No plant benchmarks were available for 2,4,6-trinitrotoluene, benzoic acid, endrin ketone, and bismuth, measured in surface soil, which may contribute to the ecological risk. The uncertainty associated with the lack of benchmark values is discussed in the Uncertainty Analysis.

Soil-dwelling Organisms

Soil-dwelling organisms, including earthworms, may be directly exposed to chemical COPCs in their soil environment. There is a potential for adverse effects to earthworms from exposure to chromium and mercury. There is potential for adverse effects to other soil-dwelling organisms from exposure to aluminum, chromium, lithium, and vanadium (Table 5-2).

No earthworm benchmarks were available for 2,4,6-trinitrotoluene, benzoic acid, endrin ketone, aluminum, antimony, lithium, silver, vanadium, and bismuth, which may contribute to the ecological risk. No other soil-dwelling organism benchmarks were available for 2,4,6-

trinitrotoluene, benzoic acid, endrin ketone, antimony and bismuth, which may contribute to the ecological risk. The uncertainty associated with the lack of benchmark values is discussed in the Uncertainty Analysis.

Meadow vole

The meadow vole may be exposed to chemical COPCs through ingestion of plants and soil. The estimated daily dose and the potential risk to a vole are presented in Table 5-3. There is a potential for adverse effects to a vole from exposure to chemical COPCs in Parcel 4 soil. Numerous metals were found to be of potential concern. For cadmium, a hazard quotient greater than unity is due to plant ingestion only. For aluminum, antimony, silver, and vanadium, hazard quotients greater than unity are due to both soil and plant ingestion. Due to the conservative method for estimating exposure doses, these risks may be overestimated as discussed further in the Uncertainty Analysis (Section 5.3).

Of these constituents, aluminum, antimony, and silver had a hazard quotient greater than 10. An uncertainty factor of 10 is typically used to extrapolate from a no observable adverse effect level (NOAEL) to a lowest observable effect level (LOAEL) (EPA, 1997; EPA, 1999). The more conservative NOAEL is the preferred screening exposure level to determine a level that is unlikely to adversely impact populations and to ensure that risk is not underestimated. If a LOAEL value is exceeded, there is more certainty that the contaminants may be adversely impacting ecological receptors.

a = EPA, 1999
 b = Baes et al., 1984 (based on Bv).
 c = Efroymsen et al., 1997
 d = TNRC, 1996.
 NA = Not applicable.
 NTV = No toxicity value available.
 ND = Not detected above method detection limit or screening level for this medium.

No mammal TRVs were available for 2,4,6-trinitrotoluene, benzoic acid, endrin ketone, bismuth, and chloride, measured in surface soil, which may contribute to the ecological risk. The uncertainty associated with the lack of TRVs is discussed in the Uncertainty Analysis (Section 5.3).

Short-tailed Shrew

The short-tailed shrew may be exposed to chemical COPCs through ingestion of earthworms and soil. The estimated daily dose and the potential risk to a shrew are presented in Table 5-4. There is a potential for adverse effects to a shrew from exposure to chemical COPCs in Parcel 4 soil. Numerous metals were found to be of potential concern. For antimony, cadmium, chromium, lithium, silver, and vanadium, a hazard quotient greater than unity is due to soil ingestion only. For aluminum, hazard quotients greater than unity are due to both soil and earthworm ingestion. Due to the conservative method for estimating exposure doses, these risks may be overestimated as discussed further in the Uncertainty Analysis (Section 5.3).

Of these constituents, aluminum, antimony, silver, and vanadium had a hazard quotient greater than 10. An uncertainty factor of 10 is typically used to extrapolate from a no observable adverse effect level (NOAEL) to a lowest observable effect level (LOAEL) (EPA, 1997; EPA, 1999). The more conservative NOAEL is the preferred screening exposure level to determine a level that is unlikely to adversely impact populations and to ensure that risk is not underestimated. If a LOAEL value is exceeded, there is more certainty that the contaminants may be adversely impacting ecological receptors.

No mammal TRVs were available for 2,4,6-trinitrotoluene, benzoic acid, endrin ketone, bismuth, and chloride, measured in surface soil, which may contribute to the ecological risk. The uncertainty associated with the lack of TRVs is discussed in the Uncertainty Analysis (Section 5.3).

White-tailed Deer

The white-tailed deer may be exposed to chemical COPCs through ingestion of plants and soil. The estimated daily dose and the potential risk to a deer are presented in Table 5-5. There is a potential for adverse effects to a deer from exposure to chemical COPCs in Parcel 4 soil. Three metals were found to be of potential concern. For silver, a hazard quotient greater than unity is due to plant ingestion only. For aluminum and antimony, a hazard quotient greater than unity is due to soil and plant ingestion. Due to the conservative method for estimating exposure doses, these risks may be overestimated as discussed further in the Uncertainty Analysis (Section 5.3).

Aluminum and antimony had a hazard quotient greater than 10. An uncertainty factor of 10 is typically used to extrapolate from a no observable adverse effect level (NOAEL) to a lowest observable effect level (LOAEL) (EPA, 1997; EPA, 1999). The more conservative NOAEL is the preferred screening exposure level to determine a level that is unlikely to adversely impact populations and to ensure that risk is not underestimated. If a LOAEL value is exceeded, there is more certainty that the contaminants may be adversely impacting ecological receptors.

No mammalian TRVs were available for 2,4,6-trinitrotoluene, benzoic acid, endrin ketone, lithium, bismuth, and chloride, measured in surface soil, which may contribute to the ecological risk. The uncertainty associated with the lack of TRVs is discussed in the Uncertainty Analysis (Section 5.3).

American Robin

A robin may be exposed to chemical COPCs through ingestion of earthworms and soil. The estimated daily dose and the potential risk to a robin are presented in Table 5-6. There is a potential for adverse effects to a robin from exposure to chemical COPCs in Parcel 4 soil. Aluminum and cadmium were found to be of potential concern. For cadmium, a hazard quotient greater than unity is due to earthworm ingestion only. For aluminum, a hazard quotient greater than unity is due to soil and earthworm ingestion. Due to the conservative method for estimating exposure doses, these risks may be overestimated as discussed further in the Uncertainty Analysis (Section 5.3).

Of these constituents, aluminum had a hazard quotient greater than 10. An uncertainty factor of 10 is typically used to extrapolate from a no observable adverse effect level (NOAEL) to a lowest observable adverse effect level (LOAEL) (EPA, 1997; EPA, 1999). The more conservative NOAEL is the preferred screening exposure level to determine a level that is unlikely to adversely impact populations and to ensure that risk is not underestimated. If a LOAEL value is exceeded, there is more certainty that the contaminants may be adversely impacting ecological receptors.

No avian TRVs were available for 2,4,6-trinitrotoluene, benzoic acid, endrin ketone, lithium, bismuth, and chloride, measured in surface soil, which may contribute to the ecological risk. The uncertainty associated with the lack of TRVs is discussed in the Uncertainty Analysis.

Northern Cardinal

A cardinal may be exposed to chemical COPCs through ingestion of plants and soil. The estimated daily dose and the potential risk to a cardinal are presented in Table 5-7. There is a potential for adverse effects to a cardinal from exposure to chemical COPCs in Parcel 4 soil. Aluminum was the only contaminant found to be of potential concern. For aluminum, a hazard quotient greater than unity is due to soil ingestion. Due to the conservative method for estimating exposure doses, these risks may be overestimated as discussed further in the Uncertainty Analysis (Section 5.3).

No constituents had a hazard quotient greater than 10. An uncertainty factor of 10 is typically used to extrapolate from a no observable adverse effect level (NOAEL) to a lowest observable adverse effect level (LOAEL) (EPA, 1997; EPA, 1999). The more conservative NOAEL is the preferred screening exposure level to determine a level that is unlikely to adversely impact populations and to ensure that risk is not underestimated. If a LOAEL value is exceeded, there is more certainty that the contaminants may be adversely impacting ecological receptors.

TRV	Toxicity reference value (mg/kg/day)	Chemical-specific	Appendix B	
log Kow	Octanol-water partition coefficient	Chemical-specific	--	

No avian TRVs were available for 2,4,6-trinitrotoluene, benzoic acid, endrin ketone, lithium, bismuth, and chloride, which may contribute to the ecological risk. The uncertainty associated with the lack of TRVs is discussed in the Uncertainty Analysis.

5.2 Risk to Aquatic Receptors

5.2.1 Radionuclides

Aquatic organisms may be exposed to radionuclide concentrations in sediment and surface water through internal exposure to water and external exposures to water and sediment. Single-media and multimedia benchmarks were used to calculate hazard quotients and hazard indices (Table 5-8 for Benner Branch surface water and Table 5-9 for Benner Branch sediment.). Single media benchmarks were used to calculate hazard quotients and hazard indices for groundwater that could potentially discharge to surface water (Table 5-10). The screening HQs and HI do not exceed unity, suggesting that the radionuclides measured in the Benner Branch and groundwater pose a negligible risk to aquatic biota.

5.2.2 Chemicals

The maximum detected concentration of aluminum in Benner Branch surface water exceeded the acute ambient water quality criteria (Table 5-11). The maximum detected concentration of chloride and fluoride exceeded background levels. No water quality benchmarks were available for these anions. No sediment contaminants exceeded the applicable probable effect levels or ER-M values, while aluminum, beryllium, lithium, molybdenum, tin, and bismuth exceeded background levels (Table 5-12). No background levels or benchmarks were available for endosulfan II and endrin ketone in sediments and no sediment benchmarks were available for aluminum, beryllium, lithium, molybdenum, tin, vanadium, and bismuth. In groundwater, the maximum detected concentrations of aluminum, arsenic, chromium, copper, iron, lithium, manganese, and zinc exceeded the acute water quality criteria (Table 5-13). No water quality criteria were available for bismuth, chloride, fluoride, nitrogen, phosphorous, and sulfate. Constituents lacking benchmarks and measured above background levels may also contribute to the ecological risk. The uncertainty associated with the lack of benchmarks is discussed in the Uncertainty Analysis.

5.3 Summary of Uncertainty

The ecological risk assessment process is subject to a variety of uncertainties. Almost every step involves assumptions based on professional judgment. Due to the conservative nature of a SLERA, most of the uncertainty results are an overestimation of risk. However, the risk may also be underestimated or unknown. Uncertainties specific to this risk assessment can be attributed to:

- Environmental chemistry and sampling analysis.
- Fate and transport parameters.
- Exposure assumptions.
- Toxicological data.

Uncertainties specific to this risk assessment include the following:

Environmental Chemistry and Sampling Analysis

- Soils collected to a two-foot depth were used in this evaluation. Except for burrowing animals, most ecological receptors will not be exposed to soil at greater than a two-foot depth. Thus, contaminant concentrations may be underestimated for burrowing animals if highest concentrations are found in samples collected below a two-foot depth.
- Chemical contaminants on the property are presumed to be present due to runoff from the Mound Plant. Off-site sources may also contribute non-radiological contamination, since the flow in the unnamed, intermittent stream channel (named Benner Branch in this document) enters Parcel 4 from the property south of Benner Road.
- The highest levels of metals contamination were measured in samples collected from the Farm Trash Area. The Farm Trash Area is located near the southwest corner of Parcel 4. It is the location of a former residence that was razed when DOE purchased the property in 1981. This area covers less than ¼ acre and was used to receive trash, tires, and household debris when the farm was in use. Mound Plant has never used this area for waste or trash disposal, and no RCRA-regulated materials have been stored or handled in the area (DOE, 1993). Thus, risks posed by contaminants found in this area may be overestimated since this area did not receive wastes associated with Mound Plant activities.

Fate and Transport Parameters

- Total (i.e., non-filtered or undissolved) surface water concentrations were used to evaluate risk for this site, though dissolved (i.e., filtered) metal concentrations more closely approximate the bioavailable fraction of metal in the water column than does the total recoverable metal (EPA, 1995). Thus, risks associated with surface water exposure may be overestimated.
- Aluminum is a major constituent in the earth's crust and is typically found at high concentrations. The soluble fraction that is easily mobile and exchangeable plays a major

role in the availability, and thus the toxicity, of this element. Generally, the soluble fraction of this element is very low in comparison to the total concentration. Thus, evaluating total concentrations of this element may overestimate risk.

- The bioavailability of COPCs in the environmental media and diet of the receptors (e.g., soil, earthworms, and plants) was estimated at 100 percent. This is likely to overestimate risk since constituents in the environment are quite frequently bound as complexes that reduce their bioavailability.
- Groundwater was assumed to discharge to surface water without dilution or attenuation of contaminants. Thus, contaminant concentrations released to surface water would be overestimated.

Exposure Assumptions

- Maximum values were used as exposure point concentrations for all media. This is likely to result in an overestimation of risk, especially for terrestrial ecological receptors who may inhabit a greater area than the area represented by just one or a few samples.
- Exposure parameters for all receptors were selected based on literature information. The amount of food, soils, sediment, and water consumed on a daily basis; the variety of food consumed; and the percentage of the whole diet that each food item represents was estimated based on information from scientific literature. In addition, the amount of time spent exposed to site-related media is assumed to be the highest possible value. Because conservative assumptions were used throughout the exposure assessment process, these assumptions are likely to overestimate dietary intake.
- Several food and water ingestion rates for bird and mammal receptors were estimated based on allometric models from the scientific literature. Allometric models that estimate dietary and water ingestion rates are based on the relationship that exists between relative body weights and ingestion rates of birds and mammals. The allometric models were developed by incorporating information on many different species that have varying weights and food preferences. These models generally result in an overestimation of the actual intake rates for ecological receptors.
- Risk to the shrew and robin was primarily associated with ingestion of earthworms. There are a number of difficulties associated with applying literature-based earthworm BAFs. Environmental conditions such as soil characteristics obscure the underlying relationship between concentrations in soil and in earthworms. Earthworms selectively feed on plant debris and soil organic matter, and consequently, soil concentrations may not represent true exposure concentrations. Also, different earthworm species bioaccumulate chemicals at different rates (Beyer, 1990). In addition, it is not known how available metals in earthworm tissues are to predators. The presence of high metal concentrations in earthworm tissues is not adequate proof that they will be absorbed by the predator (Lee, 1985). Thus, risks to the shrew and robin may be over- or under-estimated, depending on the metal evaluated and its bioavailability.

- An exposure pathway was eliminated from the quantitative evaluation in the SLERA if the pathway is incomplete (e.g., receptors cannot be exposed to the chemical); the pathway is complete but insignificant; or the pathway would be very difficult to quantify (e.g., ingestion of sediments by fish because of lack of toxicological and intake data). Several complete exposure pathways could not be quantified in this SLERA primarily because exposure assumptions and toxicity data were not available to estimate exposure and risk. There is very little information on the dermal absorption and inhalation exposure pathways for chemical COPCs. Although these exposure pathways are complete, the relative contribution to risk from these pathways when compared to that of ingestion is likely less, though the actual risk is unknown.
- While bird and mammal species at the top of the food chain have the potential to be exposed to contaminants that have biomagnified, these carnivores tend to have large home ranges that will reduce their exposure. Thus, an evaluation of potential impacts to herbivorous and insectivorous birds and mammals is expected to be more conservative since these groups would consume larger amounts of contaminated prey. Herbivores and insectivores who feed exclusively on plants or insects are expected to have a greater degree of exposure to contaminants than an omnivore who consumes a variety of prey. Thus, risk to herbivores and insectivores is acceptable, risk to an omnivore is expected to be acceptable. Although these other receptors will be exposed to contamination, this risk is expected to be less than for herbivores and insectivores, though the actual risk is unknown.
- An exposure pathway was eliminated from the quantitative evaluation in the SLERA if the pathway is incomplete (e.g., receptors cannot be exposed to the chemical); the pathway is complete but insignificant; or the pathway would be very difficult to quantify (e.g., ingestion of contaminated prey by carnivores because of lack of toxicological and intake data). Several complete exposure pathways could not be quantified in this SLERA primarily because exposure assumptions and toxicity data were not available to estimate exposure and risk. There is very little information on the dermal absorption and inhalation exposure pathways for chemical COPCs. Although these exposure pathways are complete, the relative contribution to risk from these pathways when compared to that of ingestion is likely less, though the actual risk is unknown.
- Wildlife ingestion of seep water was not quantified in the SLERA. Several organics (PETN), 1,3-dinitrobenzene, 1,3,5-trinitrobenzene, PETN, trichloroethene, and inorganics (copper, aluminum, vanadium, cobalt, and silver) were identified as COPCs in seeps in the OU5 Remedial Investigation Report, Final (Revision 0), January 1996. Only aluminum and vanadium were found in all seeps. While wildlife may ingest water from these seeps, it would not be their sole water supply because the seeps are seasonal and because small animals obtain water from a variety of sources. None of these constituents are known to biomagnify in the food chain. Thus, exposure may be slightly underestimated.

Toxicological Data

- Mammalian TRVs were not available for three organics and two anions in soil. Bird TRVs were not available for three organics, two inorganics, and two anions in soil. Surface water benchmarks were not available for six anions. Sediment benchmarks were not available for two organics, six inorganics, and one anion. Plant benchmarks were not available for three organics and one anion. Earthworm benchmarks were not available for three organics, three inorganics, and one anion. Soil organism benchmarks were not available for three organics, one inorganic, and one anion. Thus, the potential for adverse effects on terrestrial wildlife, aquatic organisms, and benthic organisms may be underestimated.
- The plant, earthworm, and soil organism benchmarks for aluminum, chromium, lithium, and vanadium are less than the site-related background concentrations for these metals. Within Parcel 4, only one sample location slightly exceeded background levels of aluminum, vanadium, and lithium. Mercury was detected at only one sample location. Antimony and chromium were measured at elevated concentrations in the Farm Trash area.
- TRVs were obtained from literature sources that were not specific to the ecological receptors at the site; therefore, in the absence of site-specific data, the extrapolation of the effect data to the receptors was necessary. Since most toxicity data were unavailable for wild bird and mammalian receptors, effects doses were obtained from laboratory studies (e.g., rat, mouse, quail, chicken, and turkey). The lowest reported chronic NOAEL for potential effects on reproduction, development, and reduced survival were used to derive TRVs when available. However, limitations in the available data necessitated the use of other endpoints such as organ-specific effects for several chemicals. This results in conservative TRVs whose relationship to potential population effects is uncertain (Sample et al., 1996). The NOAEL-based TRVs are designed not to underestimate risk, so that the risks at the site may actually be overestimated.
- The majority of available effect data was determined using laboratory animals studied under laboratory conditions. These data as well as toxicological interpretations based on blood biochemistry or body weight changes may not represent adverse health effects or cannot be precisely extrapolated to free-ranging wildlife population.
- Since toxic effects on benthic organisms, plants, earthworms, and soil organisms are species-specific and directly related to ambient conditions (e.g., pH, organic carbon content, grain size), comparison of literature-based toxic concentrations in sediment and soil is extremely simplistic and may not accurately illustrate potential hazards.

5.4 Refinement of Preliminary COPCs

To ensure that sites which may pose an ecological risk are properly identified, EPA (1996b) suggests that values used in a screening level ecological risk assessment (SLERA) should be consistently biased in the direction of overestimating risk. "Without this bias, a screening evaluation could not provide a defensible conclusion for an absence of ecological risk." The SLERA found that there is a potential for adverse effects on terrestrial organisms from residual chemical contamination (primarily select heavy metals) in Parcel 4 soils. No potential for adverse

effects from radiological contamination was found. Based on the results of this SLERA, further investigation is needed to determine if site-related chemical concentrations pose an adverse ecological threat or if the concentrations detected on-site are consistent with expected concentrations not related to site activity.

Although the SLERA probably overestimates the risk from non-radiological contaminants, further evaluation of the available site data, the terrestrial habitat on the site, the toxicity of these contaminants and the results of the Human Health Risk Assessment would have to be done to reduce that conservatism. Because of the conservative assumptions used during the SLERA, some of the retained contaminants (i.e., contaminants with an $HQ > 1$) may also pose a potential for adverse ecological effects. The constituents that pose a potential for adverse effects are summarized in Table 5-14 by area and receptor organism. The following is a description of site conditions that will reduce the conservatism of the HQs presented in the SLERA.

The area use factor is defined as the ratio of the home range (or feeding/foraging range) of the receptor to the area of contamination. Parcel 4 covers approximately 95.2 acres (38.5 hectares). For a meadow vole and short-tailed shrew, the area use factor defaults to 1 because their home range [0.027 ha – vole; 0.39 ha- shrew (EPA, 1993)] is less than the area of Parcel 4. The robin and cardinal were observed on the site during all sampling seasons; thus, no adjustment of the area use factor based on migratory habits is appropriate. Thus, the risk estimates will not change due to area use.

Maximum values were used as exposure point concentrations for all media. In order to account for uncertainties in the ability of the measured data to reflect actual site conditions, the EPA (1992) has recommended the calculation of the 95% upper confidence limit (UCL) of the arithmetic mean using log-transformed data. In most cases, it is reasonable to assume that Superfund soil sampling data are lognormally distributed (EPA, 1992). The 95% UCL concentration reasonably represents the concentration to which mobile ecological receptors will be exposed. The 95% UCL concentrations for the COPCs in Parcel 4 soil with a $HQ > 1$ (based on the maximum concentration) are presented in Tables 5-14 through 5-20. Hazard quotients were re-calculated using the 95% UCL concentration of log-normally transformed data. For the meadow vole, the re-calculated HQ exceeded unity for aluminum, antimony, cadmium, silver, and vanadium. For the shrew, the re-calculated HQ exceeded unity for aluminum, antimony, cadmium, chromium, selenium, silver, and vanadium. For the white-tailed deer, the re-calculated HQ exceeded one for aluminum, antimony, and silver. For the robin, the re-calculated HQ exceeded unity for aluminum, and cadmium. For the cardinal, the re-calculated HQ did not exceed unity for any COPC.

However, the 95% UCL concentration of aluminum (5,755 mg/kg does not exceed site-specific background concentration (19,000 mg/kg). In addition, within Parcel 4, only one sample location slightly exceeded background levels of aluminum, vanadium, and lithium. Thus, these metals can be considered to be at background levels throughout Parcel 4.

The highest levels of metals contamination (i.e., antimony, cadmium, chromium, and silver) were measured in samples collected from the Farm Trash Area (MND33-0102; MND-33-0103; MND33-0104). The Farm Trash Area is located near the southwest corner of Parcel 4. It is the location of a former residence that was razed when DOE purchased the property in 1981. This area covers less than ¼ acre and was used to receive trash, tires, and household debris when the farm was in use. Mound Plant has never used this area for waste or trash disposal, and no RCRA-regulated materials have been stored or handled in the area (DOE, 1993). Removing these data points, the maximum concentrations of antimony, cadmium, and silver do not exceed background levels and chromium slightly exceeds background at one sample location.

5.5 RISK DESCRIPTION

A screening-level ecological risk assessment was conducted at this site to evaluate which contaminants pose a potential to adversely impact ecological receptors inhabiting Parcel 4 and adjacent areas. Birds, such as the American robin and northern cardinal, and mammals, such as the meadow vole, short-tailed shrew, and white-tailed deer, which represent several trophic levels, were selected as target receptors. Direct ingestion of COPCs in soil and surface water, and indirect ingestion through the food chain via ingestion of plants and insects were considered in this assessment. External exposure through direct radiation from soil and inhalation of radionuclide-contaminated dust were also considered for radiological COPCs. Direct impacts on plants, earthworms, aquatic insects and benthic organisms were evaluated for both chemicals and radionuclides. The hazard quotient (HQ) approach was used as an indicator of the risks posed to surrogate ecological receptors from exposure to site-related contaminants. The hazard quotient compares exposure values to dose-based or media-based TRVs, and can be expressed as the ratio of a potential exposure level to the TRV: A hazard quotient exceeding 1.0 indicates the species of interest (or the species for which the toxicity data was based on) may be at risk of an adverse effect from the particular COPC, exposure route, or medium on which the HQ was based. Further evaluation may be needed in terms of site-specific toxicity data for a given target receptor. While there is potential risk to aquatic receptors exposed to chemical contaminants in Benner Branch and to plants and earthworms exposed to chemical contaminants in soil, this risk is minimal, and many of the contaminants of concern may be present due to naturally occurring or anthropogenic sources.

The conservative screening level ERA found that there is a potential for adverse effects on terrestrial organisms from residual chemical contamination (i.e., metals). However, refinement of the preliminary COPCs found that the potential for adverse ecological effects due to site-related waste disposal activities is low. The refinement included a background evaluation, recalculation of HQs using an average exposure point concentration (i.e., 95% UCL), evaluation of bioavailability of COPCs, adjustment of the area use factor, and a re-evaluation of ecological screening levels. Table 5-21 shows the ecological risk results exceeding an HQ>1. The table then compares the HQ against its refined HQ.

Note:

Total HQ may not equal sum of individual HQ because only HQ > 1 values are presented and values are rounded to three significant figures.

Although the SLERA probably overestimates the risk from non-radiological contaminants, further evaluation of the available site data, the terrestrial habitat on the site, the toxicity of these contaminants and the results of the Human Health Risk Assessment would have to be done to reduce that conservatism. Because of the conservative assumptions used during the SLERA, some of the retained contaminants (i.e., contaminants with an HQ>1) may appear to pose a potential for adverse ecological effects. The following is a description of site conditions that will reduce the conservatism of the HQs presented in the SLERA.

Exposure Point Concentration (EPC)

Maximum values were used as exposure point concentrations for all media. In order to account for uncertainties in the ability of the measured data to reflect actual site conditions, the EPA (1992) has recommended the calculation of the 95% upper confidence limit (UCL) of the arithmetic mean using log-transformed data. In most cases, it is reasonable to assume that Superfund soil sampling data are lognormally distributed (EPA, 1992). The 95% UCL concentration reasonably represents the concentration that mobile ecological receptors will be exposed to. Re-calculating the hazard quotient with the 95% UCL concentration, the re-calculated HQ for the meadow vole exceeded one for aluminum, antimony, cadmium, silver, and vanadium; the re-calculated HQ for the shrew exceeded one for aluminum, antimony, cadmium, chromium, lithium, silver, and vanadium; the re-calculated HQ for the white-tailed deer exceeded one for aluminum, antimony, and silver; the re-calculated HQ for the robin exceeded one for aluminum, and cadmium; and the re-calculated HQ for the cardinal did not exceed one for any COPC.

Background (BKG)

The 95% UCL concentration of aluminum (10,590 mg/kg) does not exceed site-specific background concentration (19,000 mg/kg). In addition, within Parcel 4, only one sample location slightly exceeded background levels of aluminum, vanadium, and lithium.

Not Site Related (NSR)

The highest levels of metals contamination (i.e., antimony, cadmium, chromium, and silver) were measured in samples collected from the Farm Trash Area (MND33-0102; MND-33-0103; MND33-0104). The Farm Trash Area is located near the southwest corner of Parcel 4. It is the location of a former residence that was razed when DOE purchased the property in 1981. This area covers less than ¼ acre and was used to receive trash, tires, and household debris when the farm was in use. Mound Plant has never used this area for waste or trash disposal, and no RCRA-regulated materials have been stored or handled in the area (DOE, 1993). Removing these data points, the maximum concentrations of antimony, cadmium, and silver do not exceed background levels and chromium slightly exceeds background at one sample location. Also, antimony, cadmium, and silver were only measured above detection limits in samples collected from the Farm Trash Area of Parcel 4.

APPENDIX C

TOXICITY REFERENCE VALUES

**Bird Toxicity Reference Values
Parcel 4, Mound Plant
Miamisburg, Ohio**

Analyte	Test Species	Dose	Duration and Endpoint	Uncertainty Factor	TRV	Reference
Organics (ug/kg-BW-day)						
2,4,6-Trinitrotoluene	NDA	--	--	--	--	--
Benzoic acid	NDA	--	--	--	--	--
Di-n-butylphthalate	Ringed dove	1100	Chronic LOAEL (reproduction)	0.1	110	Sample et al., 1996
Endrin ketone	NDA	--	--	--	--	--
Inorganics (mg/kg-BW-day)						
Aluminum	ringed turtle dove	110	Chronic NOAEL	1	110	EPA, 1999
Antimony	NDA	--	--	--	--	--
Arsenic	Brown-headed cowbird	2.46	Chronic NOAEL	1	2.46	EPA, 1999
Cadmium	Mallard drake	1.45	Chronic NOAEL	1.0	1.45	EPA, 1999
Chromium (trivalent)	Black duck	1.0	Chronic NOAEL	1	1.0	EPA, 1999
Copper	1-day old chicks	46.97	Chronic NOAEL (growth)	1.0	46.97	EPA, 1999
Lithium	NDA	--	--	--	--	--
Mercury	Coturniz quail	325	Acute LOAEL (mortality)	0.01	3.25	EPA, 1999
Selenium	Mallard	0.5	Chronic LOAEL (mortality)	1.0	0.5	EPA, 1999
Silver	Mallard	1780	Subchronic NOAEL	0.1	178	EPA, 1999
Thallium	Starling	35	Acute LD50	0.01	0.35	EPA, 1999
Vanadium	Mallard	11.4	Chronic NOAEL	1.0	11.4	Sample et al., 1996

Bird Toxicity Reference Values
Parcel 4, Mound Plant
Miamisburg, Ohio

Analyte	Test Species	Dose	Duration and Endpoint	Uncertainty Factor	TRV	Reference
Anions (mg/kg-BW day)						
Bismuth	NDA	--	--	--	--	--
Chloride	NDA	--	--	--	--	--
Fluoride	Screech owl	7.8	Chronic NOAEL	1	7.8	Sample et al., 1996
Sulfate	NDA	--	--	--	--	--

Notes:

NDA - No data available.

NOAEL - No observable adverse effect level.

LOAEL - Lowest observable adverse effect level.

NOAEL values were estimated from LOAEL values by multiplying by a factor of 0.1 (EPA, 1999).

Chronic values were estimated from subchronic values by multiplying by a factor of 0.1 (EPA, 1999).

No effect levels and effect levels are considered to be the same as a NOAEL and a LOAEL, respectively.

Acute NOAEL values were converted to chronic NOAEL values by multiplying acute values by a factor of 0.01 (EPA, 1999).

LD50 values were converted to chronic NOAEL values by multiplying the LD50 by 0.01 (EPA, 1999).

**Mammal Toxicity Reference Values
Parcel 4, Mound Plant
Miamisburg, Ohio**

Analyte	Test Species	Dose	Duration and Endpoint	Uncertainty Factor	TRV	Reference
Organics (ug/kg-BW-day)

Total Soil Ingestion Exposure (mrad/d)									6.23E-03	1.40E-04	1.21E-07	6.23E-03	1.40E-04	1.52E-07	6.37E-03

Parameter	Value	Units
Ding	Internal dose rate from ingestion of contaminated prey and soil	mrad/day
Csoil, l	Activity of radionuclide in surface soil	pCi/g
Cfa	Conversion factor to change MeV/nt to g mrad/pCi d	5.12E-02
$\xi_i, \alpha, \beta, \gamma$	Energy for α, β, γ emissions by nuclide i	Me V/nt
AF	Absorption factor	unitless
QF	Quality factor to account for the greater biological effectiveness of α particles	20 unitless, α
QF	Quality factor to account for the greater biological effectiveness of α	1 unitless, β, γ

Table D-4
Internal Exposure: Ingestion of Prey - Mammal Receptor Group D
Parcel 4, Mound Plant
Miamisburg, Ohio

Ding = Σ QF * C_{soil} * C_f * C_{fa} * AF

APPENDIX E

THREATENED AND ENDANGERED SPECIES INFORMATION

RECEIVED
MAY 30 2000

Bob Taft • Governor

Samuel W. Speck • Director

Division of Natural Areas and Preserves

Stuart Lewis • Acting Chief

May 23, 2000

Roy F. Weston, Inc.
Terry Bosko
3 Hawthorn Parkway
Suite 400
Vernon Hills, IL 60061

Dear Ms. Bosko:

I have reviewed our Natural Heritage maps and files for the Mound Plant project area, including a one mile radius, on the Miamisburg and Franklin Quads in Montgomery County, Ohio. We have one record within the project area. The location for Inland Rush (*Juncus interior*), a state threatened plant, is marked by a red dot on the accompanying map.

There are no existing or proposed state nature preserves or scenic rivers at the project site. We are also unaware of any unique ecological sites, geologic features, breeding or non-breeding animal concentrations, champion trees, or state parks, forests or wildlife areas within a one mile radius of the project area.

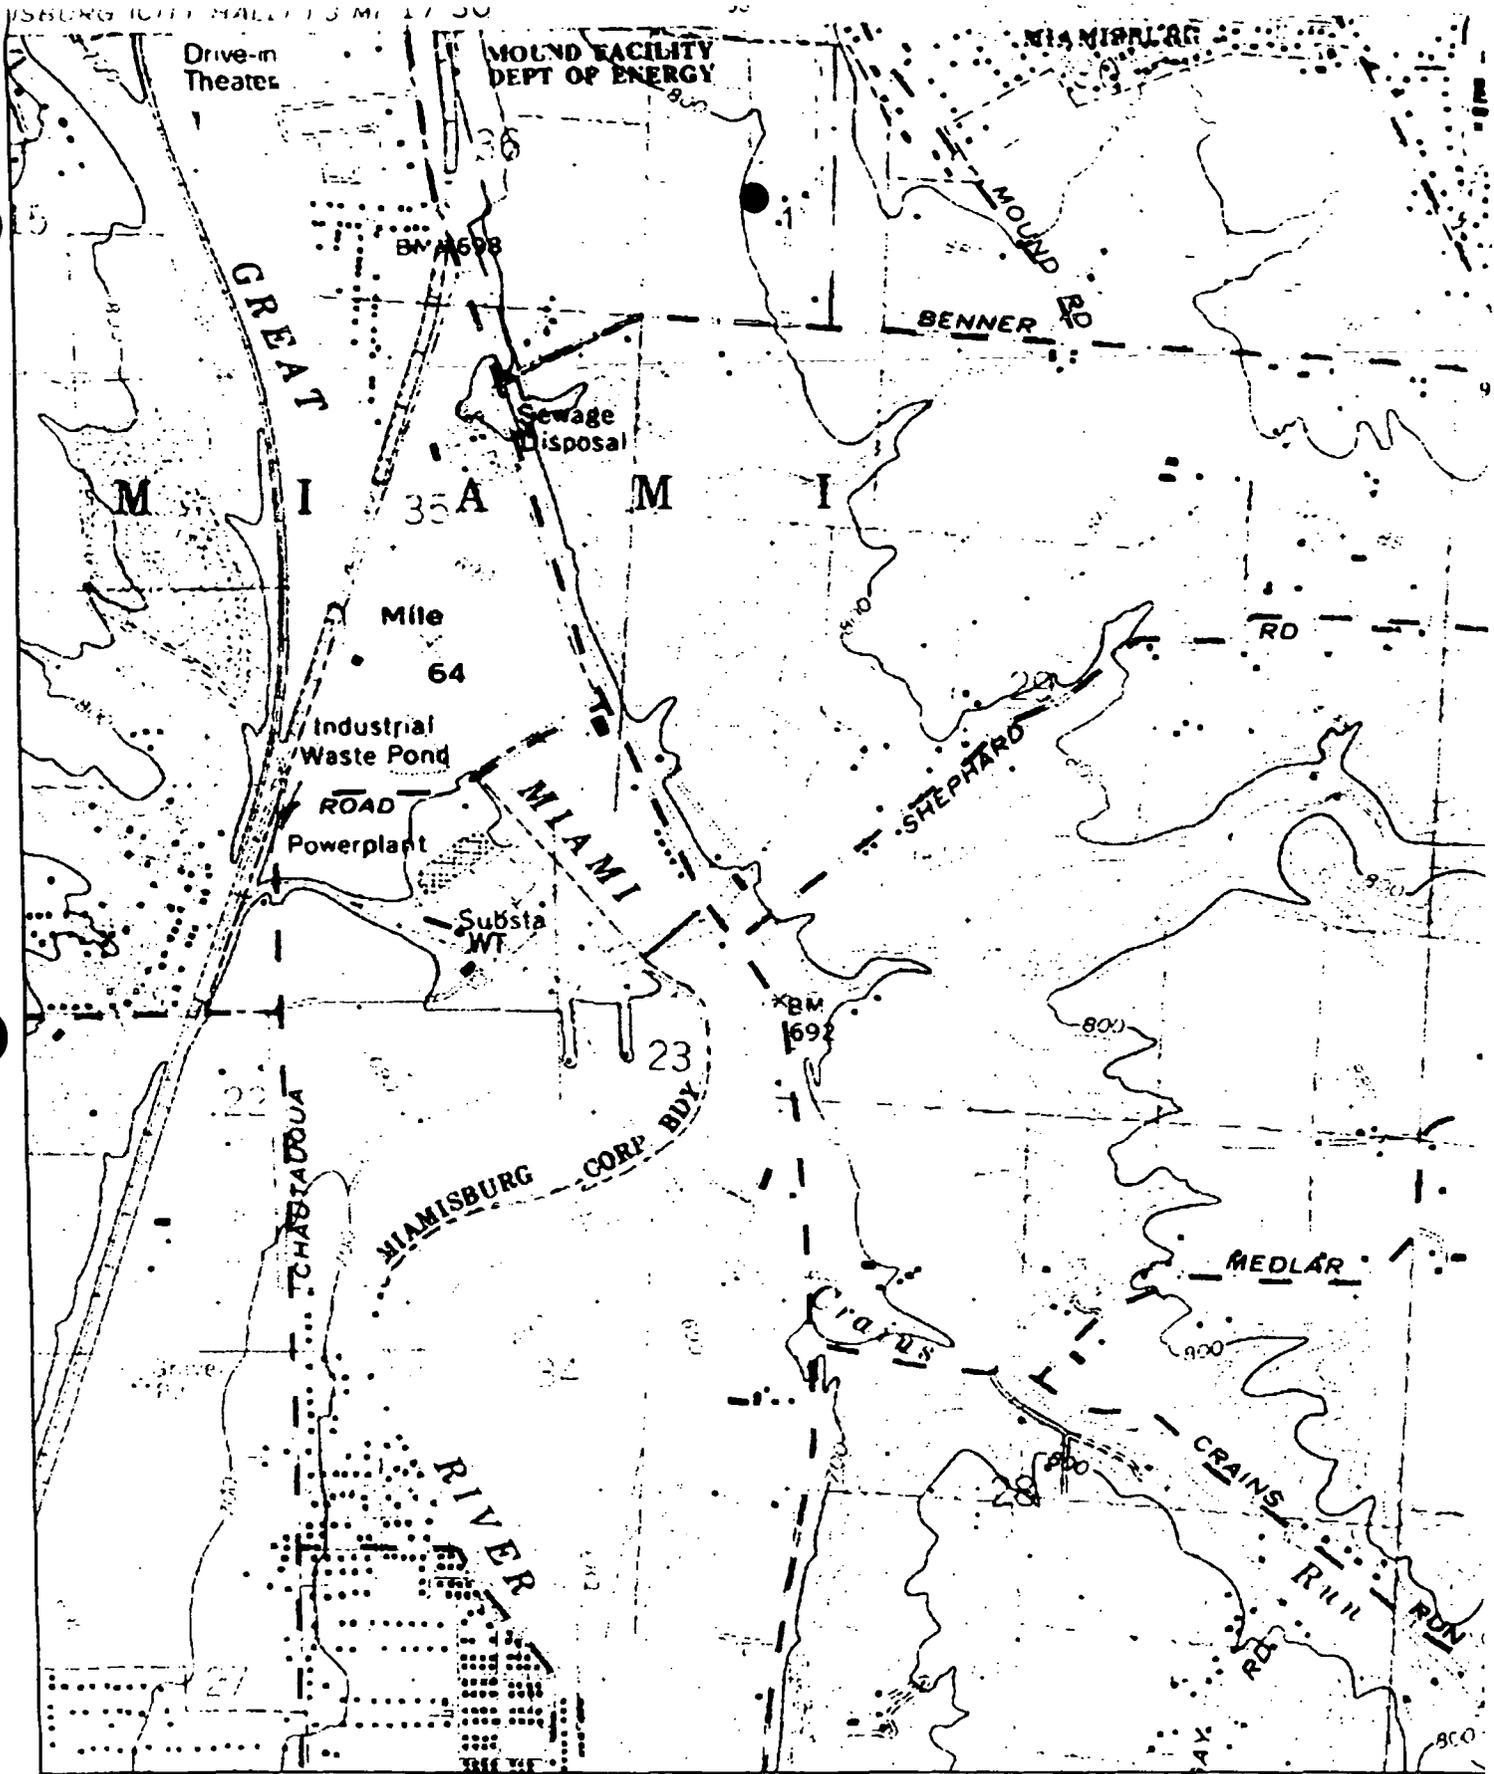

Our inventory program has not completely surveyed Ohio and relies on information supplied by many individuals and organizations. Therefore, a lack of records for any particular area is not a statement that rare species or unique features are absent from that area. Please note that although we inventory all types of plant communities, we only maintain records on the highest quality areas. Also, we do not have data for all Ohio wetlands. For additional information on wetlands and National Wetlands Inventory maps, please contact Jim Given in the Division of Real Estate and Land Management at 614-265-6770.

Please contact me at 614-265-6818 if I can be of further assistance.

Sincerely,

Debbie Woischke, Data Specialist
Division of Natural Areas & Preserves

Mission: To ensure a balance between wise use and protection of our natural resources for the benefit of all.

Mr. Terry Bosko
Roy F. Weston, Inc.
Suite 400
3 Hawthorn Pkwy
Vernonn Hills, IL 60061-1450

Dear Mr. Bosko:

This is in response to your May 22, 2000 letter requesting information we may have regarding the occurrence or possible occurrence of Federally-listed threatened or endangered species within the vicinity of the proposed site. This information is being requested to prepare a Screening Level Ecological Risk Assessment for the Miami-Erie Canal and the South Property of the Mound Plant for the U.S. Department of Energy as part of CERCLA activities at the plant. The plant is located in Miamisburg, Montgomery County, Ohio.

In general, we recommend that proposed developments minimize water quality impacts and impacts to high quality fish and wildlife habitat, such as forests, streams, and wetlands. If streams and wetlands would be impacted, the Louisville District of the Corps of Engineers should be contacted for possible need of a Section 404 permit.

ENDANGERED SPECIES COMMENTS: The proposed project lies within the range of the Indiana bat, a Federally listed endangered species. Summer habitat requirements for the species are not well defined but the following are thought to be of importance:

1. Dead trees and snags (especially those with exfoliating bark) which may be used as maternity roost areas along riparian corridors.
2. Live trees (such as shagbark hickory) which have exfoliating bark.
3. Stream corridors, riparian areas, and nearby woodlots which provide forage sites.

Considering the above items, we recommend that if trees with exfoliating bark (which could be potential roost trees) are encountered along the proposed right-of-way, they should be saved wherever possible. If they must be cut, they should not be cut between April 15 and September 15.

If desirable trees are present and if the above time restriction is unacceptable, mist net or other surveys should be conducted to determine if bats are present. The survey should be designed and conducted in coordination with the endangered species coordinator for this office, Mr. Buddy Fazio. The survey should be conducted in June or July since the bats would only be expected in the project area from approximately April 15 to September 15.

The project area also lies within the range of the eastern massasauga, a docile rattlesnake that is declining throughout its national range and may soon receive status as a Federal candidate species. The snake is currently listed as endangered by the State of Ohio, and ultimately may become a Federally listed species. We encourage early project coordination to avoid potential impacts to massasaugas or their habitat.

The massasauga is often found in or near wet areas, including wetlands, wet prairie, or nearby woodland or shrub edge habitat. Wet habitat and nearby edges are utilized by the snakes especially during spring and fall. Upland areas up to 1.5 miles away are utilized during summer, if available. If crayfish holes exist in a wet area, the massasauga may live there, too. Some project management ideas include the

following:

1. At a minimum, project evaluations should contain delineations of whether or not massasauga habitat occurs within project boundaries. Descriptions should indicate the quality and amount of massasauga habitat that may be affected by the project.
2. In cases where massasaugas are known to occur or potential habitat is rated moderate to high, massasauga surveys may be necessary. If surveys are conducted, they should be performed during the period of Spring emergence from dens (usually a narrow window in April or May).
3. In portions of projects where massasaugas will be affected, clearing and construction activities should occur during Summer when air and ground temperatures are above 65° F. Massasaugas are mobile during this period and are more likely to move to upland sites.
4. Maintenance activities (mowing, cutting, burning, etc.) should be conducted within the specified seasonal temperature periods described.

This technical assistance letter is submitted in accordance with provisions of the Fish and Wildlife Coordination Act (48 Stat. 401, as amended; 16 U.S.C.661 et seq.), the Endangered Species Act of 1973, as amended, and is consistent with the intent of the National Environmental Policy Act of 1969, and the U.S. Fish and Wildlife Service's Mitigation Policy.

If you have questions, or if we may be of further assistance in this matter, please contact Megan Sullivan at extension 21 in this office.

Sincerely,

for Kent E. Kroonemeyer
Supervisor

SUBJECT: Contract No. DE-AC24-97OH20044
PARCEL 4 CERCLA DOCUMENTS – FINAL

REFERENCE: Statement of Work Requirement C.7.1e—Regulator Reports

Dear Mr. Provencher:

Rob Rothman of your office has approved the release to USEPA, OEPA, ODH, MMCIC, the administrative record, and the Public Reading Room of the Final version of the following documents for Parcel 4:

Human Health Residual Risk Evaluation (RRE)
Ecological Risk Evaluation (ERE)
Record of Decision (ROD)
Environmental Summary (ES)

If you have any questions regarding the documents, or if additional support is needed, please contact Dave Rakel at extension 4203.

Sincerely,

Jeffrey S. Stapleton
Manager, Environmental Safeguards & Compliance
