1.0 Introduction

1.1 Background

This sampling and survey report evaluates the final status survey data collected in Building 779, Annex A, both by the Rocky Flats Environmental Technology Site's (RFETS) Contractors (Kaiser-Hill, Rocky Mountain Remediation Services, L.L.C., and their subcontractors, hereafter referred to as the Contractor) and by MACTEC-ERS, the independent verification contractor (IVC). Data collected by the IVC is designed to independently assess and verify the RFETS' compliance with the approved derived concentration guideline levels (DCGLs) established for the buildings in the 779 Cluster. Data collected by the Contractor has been reviewed by the IVC and compared with the independent verification data collected by the IVC.

The sampling and survey data collected has been compared with the approved surface contamination concentration benchmark values known as DCGLs. The RFETS DCGLs for surface contamination concentration are specified in the Contractor's Closeout Radiological Survey Plan for the 779 Cluster (RMRS 1999a). The independent verification DCGLs are specified in the IVC's *Independent Verification Sampling and Analysis Plan for Building 779 Cluster* (IV SAP) (DOE 1999a).

Samples collected and surveys performed to obtain independent verification and corroboration of the RFETS sampling and survey results were collected in accordance with the U.S. Environmental Protection Agency (EPA), Colorado Department of Public Health and Environment (CDPHE), and U.S. Department of Energy (DOE) approved *Independent Verification Sampling and Analysis Plan for Building 779 Cluster* (DOE 1999a). The data is evaluated herein principally on the Multi-Agency Radiation Survey and Site Investigation Manual (MARSSIM) data quality assessment methods, conventional guidance from EPA, and accepted practice and methods used in radiological site assessment and characterization. Principal guidance documents include:

- *Multi-Agency Radiation Survey and Site Investigation Manual* (EPA 1997)
- *Data Quality Objectives Process for Superfund* (EPA 1993)
- *Guidance for Data Quality Assessment—Practical Methods for Data Analysis* (EPA 1998)
- *Manual for Conducting Radiological Surveys in Support of License Termination* (NRC 1992)
- *A Nonparametric Statistical Methodology for the Design and Analysis of Final Status Decommissioning Surveys* (NRC 1995)

A common theme in these guidance sources is the use of a seven-step data quality objective (DQO) activity as the foundation for the sampling and analysis plan (SAP) development and subsequent data evaluation.

Following this introductory background is a discussion of Annex A history and an overview of the assessment and independent verification process used. Section 2 describes the field methods and procedures used to collect data. Section 3 presents the sampling results and summary

statistics for each subset of data. It also describes the data reduction process used and statistical comparisons of the data subsets and their significance. Section 4 presents the sampling results in the context of compliance with the benchmark values and Section 5 presents the survey and sampling results in a graphic format for easier visualization. Evaluation of the Contractor's Final Status Radiological Survey, computations, and conclusions are presented in Section 6. The IVC collected data are compared to their respective DQOs in what is termed the Data Quality Analysis in Section 7. Section 8 summarizes the data quality analysis, provides objective assessment of the concentrations of residual contamination found in the building, and offers conclusions and recommendations for disposition of the building. Appendices are included to provide additional detail where appropriate.

The risk manager and decision maker for this project is DOE-Rocky Flats Field Office (DOE-RFFO).

1.2 Building 779 History

The Building 779 Cluster is located on DOE's Rocky Flats site near Golden, Colorado. The site is a former nuclear weapons production facility. The various process facilities and laboratories were grouped together with their various support buildings and structures and identified as "clusters," with the building number of the principal building as the cluster name (e.g., the Building 779 Cluster). The 779 Cluster was primarily used for research and development activities and supported a number of various operations as part of the research and development mission including: 1) process chemistry technology, 2) physical metallurgy, 3) machining and gauging, 4) joining technology, and 5) hydriding operations. No processes or operations are now active.

Annex A and the loading dock are single-level structures that are connected to the north and east side of Building 779. Annex A contained numerous laboratories and support facilities that were utilized for nuclear weapons research and development. The exterior walls of Annex A are cinder block and concrete. The exterior walls of the loading dock are galvanized steel, cinder block and concrete.

1.3 Current Condition of Annex A

Annex A underwent a decontamination and decommissioning (D&D) process to ready it for final status radiological survey. In the D&D process, the building was stripped of utility services, and equipment and penetrations were removed or cut flush with the walls. All penetrations in the slab were grouted and will remain until environmental restoration is accomplished. One contaminated slab penetration (approximately 12 inches by 12 inches) had a metal frame with fixed contamination. The penetration could not be easily decontaminated and was therefore grouted and a plate was affixed over the penetration and imbedded metal frame. The plate will be labeled and painted orange by the contractor prior to demolition to indicate the presence of radioactive contamination. All other areas where contamination was detected were decontaminated by the contractor prior to conducting the final survey. Numerous floor, walls and ceiling surfaces were hydrolased to remove paint. The interior of Annex A and the loading dock was subdivided into ten survey units. The IVC randomly selected two of the ten units as part of the overall Building 779 independent verification. At the request of the Contractors, the IVC has prepared this stand-alone report for Annex A.

1.4 Overview of the Assessment and Independent Verification Process

The approach used to independently determine whether Annex A met the mean, or average, benchmark release criteria (derived concentration guideline level-average concentration [DCGL_w]) followed the MARSSIM method. Five of 41 survey units identified in Building 779 were selected for actual measurement by the IVC. In this case, survey units 779-21 and 779-23 (Annex A) were two of the five selected for independent verification, thus meeting the contractual requirement to assess 5 to 10 percent of the Contractor's results. The IVC used oversight of the Contractor's scanning surveys and a critical review of the data collected by the Contractor to independently determine compliance with the maximum concentration benchmark release criteria (derived concentration guideline level-elevated measurement comparison [DCGL_{EMC}]).

The first step in the process to independently assess the Contractor's basis for decision on the disposition of Annex A was to review the Contractor's *Closeout Radiological Survey Plan for the 779 Cluster* (RMRS 1999a) and associated D&D planning documents. All comments and issues raised by the IVC were reported to DOE-RFFO and were addressed by the RFETS Contractor and implemented in the final status survey plan, as necessary.

The Contractor's SAP establishes the criteria which, when met, represent acceptable levels of risk from exposure to residual contamination which might be present in the building. DOE-RFFO, EPA, and CDPHE agreed upon surface contamination concentration criteria below which further remedial action would not be warranted. These criteria, or DCGLs, serve as the benchmarks against which the building surfaces were to be measured. The Contractor's DCGLs are:

- The mean removable alpha surface contamination concentration in the selected survey unit(s) is below 20 disintegrations per minute (dpm)/100 square centimeters (cm²).
- The mean total alpha surface contamination concentration attributable to transuranic radioactivity as measured by direct surface emission in the selected survey unit(s) is below 100 dpm/100 cm² (averaged over 1 square meter [m²]).
- The mean total alpha surface contamination concentration attributable to uranium series radioactivity¹ as measured by direct surface emission in the selected survey unit(s) is below 1,000 dpm/100 cm² (averaged over 1 m²).
- The maximum total alpha surface contamination concentration attributable to transuranic radioactivity as measured by direct surface emission in the selected survey unit(s) is below 300 dpm/100 cm².
- The maximum total alpha surface contamination concentration attributable to uranium series radioactivity as measured by direct surface emission in the selected survey unit(s) is below 5,000 dpm/100 cm².

¹In cases where isotopic composition is not determined, the SAP requires the application of the more restrictive limits associated with the transuranic series radionuclides.

- The mean total alpha contamination concentration attributable to transuranic radioactivity on and beneath a surface with a surface coating as measured by collection and analysis of a surface media sample in the selected survey unit(s) is below 100 dpm/100 cm².
- The mean total alpha contamination concentration attributable to uranium series radioactivity on and beneath a surface with a surface coating as measured by collection and analysis of a surface media sample in the selected survey unit(s) is below 1,000 dpm/100 cm².

After reviewing the Contractor's SAP, an IV SAP was constructed. The IV SAP was developed in consultation with DOE-RFFO, EPA, and CDPHE. It was designed to detect and measure the concentration of the radioactive contamination remaining in survey units selected for independent verification such that statistically appropriate analyses could be used to determine whether the results obtained by the Contractor in the same survey unit could be verified or corroborated by the IVC. The IV SAP alone does not collect enough data to make the required decision for the entire building but provides sufficient data for critical comparison with the Contractor's conclusion in a single survey unit. In the case of Annex A, the IVC performed surveys and sampled two of ten possible interior survey units (779-21 and 779-23) identified by the Contractor.

The next step was to observe and evaluate the Contractor's implementation of the final status survey against the criteria established in the SAP. The IVC Health Physicist is permanently assigned to Rocky Flats and works on site to observe the Contractor's sampling and survey methods and review analytical processes.

The fourth element of the independent verification process was to provide blind matrix samples to the Contractor for inclusion in their sample batches from Building 779 Cluster. The blind samples included both blanks and spikes of smear filter paper matrices and surface media matrices. Blind matrix samples are being included in the Contractor's sample batches from Building 779 as the Contractor's manpower and schedule permits. It is important to note that it is not critical to the sampling objective to introduce Stage-I quality control samples to a particular batch of the Contractor's samples or even while they are sampling a particular building or survey unit being considered for independent verification.

Finally, and with the approved IV SAP, the sampling plan was executed. The IVC collected samples and performed measurements in the selected survey units in order to corroborate the results obtained by the Contractor. The measurements and samples were obtained in accordance with the *Independent Verification Sampling and Analysis Plan for Building 779 Cluster* (DOE 1999a).

The field data was reviewed in the field with representatives from DOE and the Contractor. The EPA and CDPHE have been apprized of the results of independent verification field data collected. Field data was recorded both on paper (Appendix D) and electronically (Appendix H). Following data collection, the data was verified and reduced so that the appropriate comparisons and analyses could be conducted. The presentation of the results of the field sampling are detailed in this report along with the IVC's recommendations and verification of Annex A final status survey results.

2.0 Field Investigation

2.1 Mobilization

Prior to mobilizing the independent verification sampling team at the site, each member of the team was provided with a copy of the IV SAP and was trained on the field sampling equipment and procedures to be used. The Contractor made detailed measurements of the building and supplied simple architectural drawings of the survey units in Annex A (779-21 and 779-23) to be used in laying out the sampling grids and sample locations.

Mobilization to the field began the week of October 5, 1999, for survey unit 779-21 and the week of October 25, 1999, for survey unit 779-23. The sampling team personnel had completed all required RFETS training necessary to support the sampling and survey work during a previous visit to RFETS. Equipment was staged and final details were arranged.

The radiation survey detectors selected for this application were gas-filled, proportional counters made by Eberline; model HP-100. Gas filled detectors are subject to response and calibration variation with changes in altitude. Consequently, the HP-100 probes were field calibrated on site at the RFETS altitude and using RFETS supplied counting gas. The instrument and probe package was response checked and verified to be in working order and within the parameters established in the SAP. The surface media sampling tool was tested and test measurements were made confirming the suitability of the measurement protocol. A walk-through of the building was made to assess the condition of the building, to identify any intrinsic safety issues, and to compare the building structure and features with the assumptions made and procedures outlined in the SAP. It was concluded that the assumptions used to develop the SAP and its associated procedures were consistent with the conditions existing in the building and that the procedures developed for characterizing the contaminant concentrations in the building accounted for these conditions.

2.2 Field Selection of Survey Units for Independent Verification

The first step in the sample allocation strategy was to select from among the 41 survey units available in Building 779 those survey units to be sampled and surveyed by the IVC. The random selection process assigned greater weighting or priority to survey units with a classification indicating greater potential to exceed the allowable radiological concentration. Table 2-1 lists the 41 survey units identified by the Contractor for Building 779 (RMRS 1999b). A simple, commercially available, spreadsheet program with a random number generation feature was used to randomly select the survey units to be independently verified. Appendix A contains a printout of the survey units selected by the computer generated random number method. Survey units 779-21 and 779-23, Annex A, that included rooms 143, 144, 145, 146, 147, 148, 151, and 152, were two of five units selected for Building 779.

2.3 Field Identification of Sample Locations

Once the survey units to be verified had been selected, the proposed location of each measurement and sample was laid out using the sample allocation protocol specified in the SAP. Drawings of the survey units were created with the walls and ceiling "unfolded" and set flat to

Table 2-1. Survey Units Identified for Building 779

Survey Unit Description	Survey Unit #	Survey Classification	Weight Factor
Rooms 170/172 Floor and Lower Walls (including Mezzanine above Room 172)	779-01	Class 1	6

By assigning weighting factors to the survey units based on radiological classification, the independent verification survey will preferably select survey units which have a higher probability of exceeding the applicable DCGLs. Class 1 survey units (the most likely to be contaminated) are three times more likely to be selected than Class 2 units and six times more likely than Class 3 units.			

assist the process of spatial distribution and sample location recording. The survey units were then divided by a 2-meter sampling grid superimposed over the surface of the survey units. Figure 2-1 shows the sample grid layout for survey units 779-21 and 779-23.

The selection and distribution of sampling locations within each survey unit was made using the protocol approved in the SAP including:

- Random selection of the sampling starting point within the selected survey unit(s) (Appendix A),
- Systematic distribution of sample locations within the selected survey unit(s) to ensure representative spatial coverage of the survey unit, and
- Personnel safety during the execution of the sampling plan

Drawings of each surface within the survey unit and actual sample locations as determined in the field are shown on Figure 2-2. After the sample locations were allocated, an inspection of each survey unit was conducted to ensure that each sample location selected could be accessed and sampled safely. Three sample locations in survey unit 779-21 were relocated in accordance with the sample relocation protocol outlined in the SAP due to safety issues. The samples relocated are annotated on the drawings in Figure 2-2.

Sample locations were next laid out on the building surfaces within the survey units. Each sample location was measured out and marked on the surface with a permanent marker. Unique alpha-numeric bar codes (Figure 2-3) were affixed to the surface adjacent to the selected sample location. A duplicate bar code was affixed to the field data sheet and the bar code number was recorded on a copy of the survey unit drawings. It should be noted that all sample locations were selected without prior knowledge of contaminant concentrations in the area and before radiological survey instruments were employed. In this way, sample locations were not biased.

2.4 Sampling Equipment and Procedures

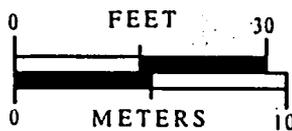

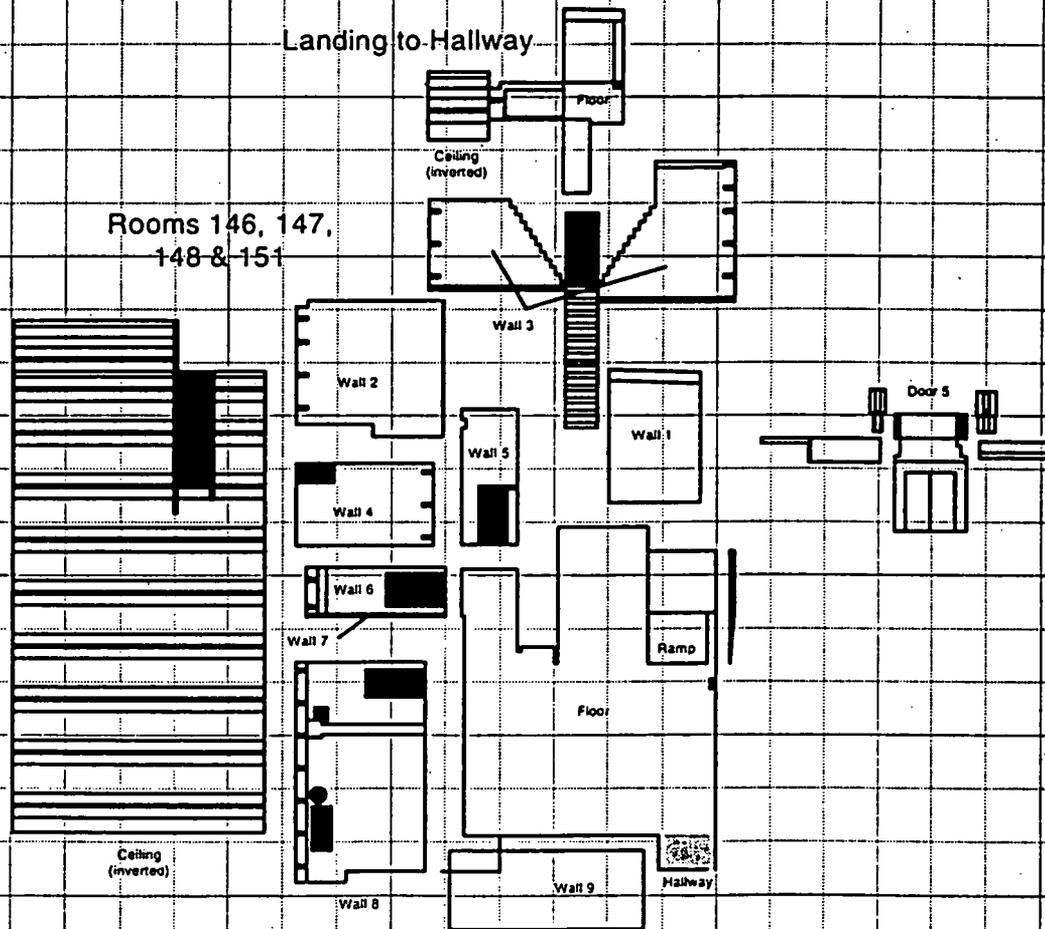

2.4.1 Radiological Instrumentation

The field measurement instrument used for measuring surface deposited radiological contamination was the Eberline, E-600 Smart Portable Multi-purpose Radiation Survey Instrument with a modified Eberline HP-100 gas proportional detector probe. The detector was fitted with an Eberline "Smart Pack" to convert the conventional detector to be compatible with the microprocessor based E-600 and to electronically store the probe's calibration data. The probe's alpha channel was calibrated to a plutonium-239 (Pu-239) National Institute of Standards and Technology (NIST) traceable calibration source. The calibration certificate for the source is provided in Appendix B and the calibration data sheets for the instruments are provided in Appendix G. Figure 2-4 shows the configuration used to measure the alpha surface emission activity on the surfaces in the survey unit. The direct measurement data was collected in accordance with the procedure outlined in the SAP.

2.4.2 Sampling

2.4.2.1 Smear Sampling

Smears were used to wipe the surfaces in order to measure the potential for removable radioactivity on the survey unit surfaces. The IVC chose to use 47 millimeter (mm) disc smears made of a duck cloth material rather than the typical paper or cellulose fiber filters commonly used since many of the surfaces requiring measurement are very rough. The duck cloth smears are very durable and will pick-up loose contaminants from even very rough or abrasive surfaces without disintegrating. The smear samples were collected after the direct static surface measurements were obtained. The technician wiped the surface within the 100 cm² sample area applying moderate pressure. Each smear was placed individually into a glassine envelope to

prevent cross contamination and static charge induced migration of contaminants. Each glassine envelope containing a smear sample was then over-packed in a small sealable plastic bag and then in a manila sample envelope. The envelope was then marked with a bar code label linking it to the sample location from which it was obtained, and entered into a sample custody system to preserve sample integrity for subsequent analysis at the Grand Junction Office (GJO) Analytical Laboratory. The smear samples were secured in a sample box sealed with tamper-evident custody seals at the sample site until the field sampling was complete and then transported to the GJO Analytical Laboratory.

In all, 29 smear samples were collected from each survey unit—one at each of the 29 survey locations. These were submitted to the GJO Analytical Laboratory for radiological analysis. The results of these measurements are summarized in Section 3 and the laboratory analytical report is contained in Appendix C.

2.4.2.2 Surface Media Sampling

Paint and other surface coatings or residues present on the surfaces of the building presented an obstruction to detection and measurement of the radioactive surface contamination which might have been present. To assess the potential for, and measure the concentration of, contaminants which might be present in and/or beneath painted or coated surfaces, a "vener" of the surface (including any surface coating or residue) was removed. When there was no surface coating or residue present, but the radiological measurement of the surface exceeded the *a priori* estimate of the critical detection level of 22 dpm/100 cm², a veneer of the substrate was collected to assess the potential for a near-surface contamination layer embedded in a porous surface. A disposable plastic containment was erected over the selected sample location. A heavy duty, rotary impact drill (Figure 2-5) was fitted with a special bit designed to pulverize the surface without drilling into it. The bit was inserted through a port in the containment. Only the bit penetrated the containment. The impact tool was moved over the surface removing the thinnest possible layer until all surface coating within the 100 cm² sample area was removed.

To be inserted later—PHOTO OF THE DRILL AND BIT

Figure 2-5. Photo of Rotary Impact Drill and Bit

The surface material removed (the sample) was collected in the bottom of the plastic containment. The technician collected the removed media as a sample. The sample was then transferred to a small sealable plastic vial. A bar code label linking the sample location from which it was obtained was affixed to the vial and entered into a sample custody system to preserve sample integrity for subsequent analysis at the GJO Analytical Laboratory (see Figure 2-6). The vials were placed in a sealable plastic bag and secured in a sample box sealed with tamper-evident custody seals at the sample site until the field sampling was complete and then transported to the analytical lab.

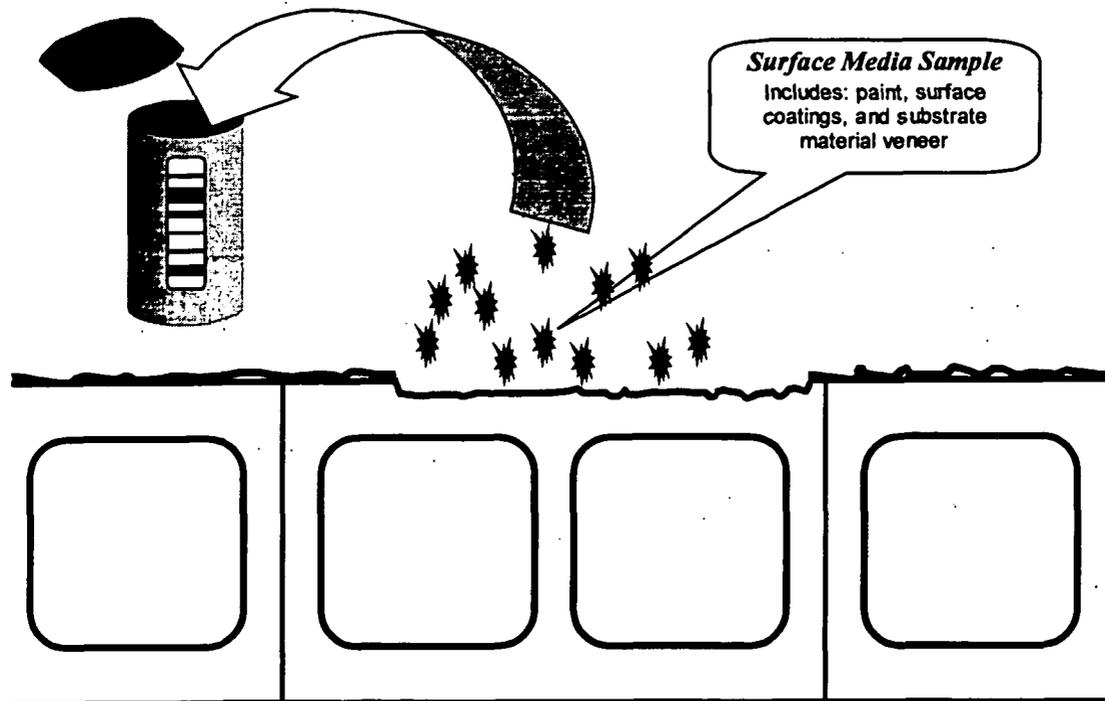

Figure 2-6. Surface Media Sample Collection

2.4.3 Laboratory Measurements

Smears and surface media samples were processed and analyzed at the GJO Analytical Laboratory using the methods and procedures identified in Tables 2-2 and 2-3 and prescribed in the IV SAP.

Table 2-2. Smear Sample Analytical Method

Laboratory Method—Gross Alpha Radioactivity	
Counting method	Gas Proportional Low-Background Alpha/Beta Counting System
Instrumentation	Canberra Model 2404

24

Based on the EPA's terminology, the methods described in Tables 2-2 and 2-3 are categorized as Analytical Level V because they are non-conventional in the EPA's Contract Laboratory Program (CLP) (EPA 1988). However, comparing the level of quality assurance and quality control (QA/QC) embodied in these procedures, they are comparable to EPA's CLP Analytical Level IV.

2.4.4 Field Measurements

2.4.4.1 Background Determination

Background was determined in the survey unit being surveyed before, and at least every 2 hours during, each sampling shift. Additionally, background measurements were collected immediately prior to, and immediately after, changing out a detector probe. In the center of the survey unit, a masonite hardboard surface (the back of a clipboard) that has essentially no inherent alpha radioactivity and which was clearly "unaffected" (i.e., clearly not part of the potentially contaminated buildings within the 779 Cluster) was used for establishing background according to the procedure detailed in the SAP. This method establishes the background associated with the instrument only. Background measurements were recorded both electronically and by hand.

2.4.4.2 Direct Static Surface Radioactivity Measurements

Each of the 29 sample locations identified within each survey unit was directly measured to assess the alpha radioactivity deposited on the surface. Direct static field measurements were made using the approved procedure in the IV SAP. Each measurement was collected for 90 seconds, in the instrument's "SCALER" operating mode, and at a fixed distance of approximately 0.125 inch (1/8th inch) from the surface. When the acquisition count time was complete, the result was read, manually recorded, and electronically logged into the instrument's memory. Direct measurement results greater than the instrument's *a priori* critical detection level (L_c) of 22 dpm/100 cm² triggered the need to collect a surface media sample even where no surface coating existed. In cases where surface media samples were indicated and collected, a second direct static measurement was made at the same location following removal of the surface veneer. Often, the direct measurement reading obtained subsequent to the veneer removal was unchanged or greater indicating the likelihood that the substrate media (typically concrete) contained an appreciable and measurable alpha background radioactivity that was attenuated by the veneer¹. In these circumstances, a field decision was made as to the need for the collection of additional surface media to determine compliance with the DCGLs. Pertinent observations regarding the nature of the surface, substrate material, or instrument response were recorded. No anomalies were noted during the direct static measurement process.

¹To avoid the need for making reference survey unit measurements to characterize and quantify natural radioactivity, background has been narrowly defined in the Contractor's Closeout Radiological Survey Plan to include only radiation measured by the instrument system operating in "free air". This definition excludes radioactivity which might be present in the building materials but which has not been contributed or added by DOE. All naturally occurring radioactivity measured during Final Status Survey is to be considered "contributed" or attributable to DOE activities and compared to the applicable DCGLs.

End of current text

26

3.0 Sampling and Survey Results

Sampling and survey results are divided into four basic categories for discussion, analysis, and comparison with the applicable DCGLs. The categories correspond to the three fundamental samples or measurements employed in the independent verification: Smear sampling, Direct Static Measurements, and Surface Media Samples. The fourth category is for QC data. QC data is presented in Section 6.0 of this report.

3.1 Direct Static Field Measurements

Direct measurements of the radioactivity emission from surfaces were made using static, 90-second counting intervals, over which the total counts were integrated. The measurements recorded were gross values normalized to $\text{dpm}/100 \text{ cm}^2$. In the context of this sampling evolution, a "gross measurement" means a measurement made with a radiation detection instrument to which no background correction has been applied. Raw or gross data is important when measurements will be used to make statistical inferences, since not all data will necessarily have the same correction factors applied to properly reduce them to meaningful numbers. Reporting gross or raw data also permits one to analyze the functionality of the instrument with which the measurement was made, and to verify the appropriateness of the data reduction process. The data reduction process for the field measurement data collected in this sampling evolution involves corrections for the efficiency of the radiation detector to the subject radiation and the instrument response to background sources of radiation (excluding surface media contribution to background).

The use of the Eberline E-600 Smart Portable Multi-purpose Radiation Survey Instrument in this application provides a platform for accommodating the probe specific factors including efficiency, high voltage, discrimination thresholds, crossover correction factors and calibration set up parameters within the detector's associated "smart pack" microchip. These correction factors are common to all of the direct field measurements made with the E-600 and HP-100 detector for this SAP. As a result of incorporating these factors, the instrument reads out and electronically logs data points directly in units of $\text{dpm}/100 \text{ cm}^2$. These readings were not, however, field corrected for background radiation.

3.1.1 Background Measurements

The assessment of an instrument's response to background radiation is important from two perspectives. First, it permits the assessment of the minimum sensitivity (detection limit) for the instrument and measurement process in the presence of background radiation. The *a posteriori* minimum detectable activity (MDA) is calculated from this actual background data. Second, by assessing the instrument's response to background radiation in terms of the units that field data will be collected, a correction can be applied to the field measurement data to permit determination of radioactivity present in excess of background. Because the naturally occurring concentrations of background radioactivity in building materials used in the construction of the buildings in the 779 Cluster were expected to be below and well within the DCGL benchmarks for radioactive contamination on building surfaces, the Contractor chose to assign all building material background radioactivity as part of the DOE contributed activity for comparison against the DCGL. As a result, no attempt was made to measure the concentrations of naturally occurring radioactivity measurable on surfaces in a "reference survey unit" or unaffected area. Still, there was the need to measure and account for the instrument's response to other sources of

background radiation (e.g., cosmic radiation) which could otherwise not be distinguished from the contaminant of concern.

To accommodate the need for correcting the instrument data for sensitivity to background radiation, excluding that present in the substrate of the surfaces being measured, instrument background measurements were collected periodically over the sampling period. In all, 54 measurements (27 in each unit) of the alpha background radiation level were recorded over the sampling period in accordance with the procedure for determining background (DOE 1999a). Each background measurement made during the sampling period is presented in Table 3-1.

Table 3-1. Direct Static Measurement Background Data, Annex A

Sample Location	Survey Unit 779-21		Survey Unit 779-23

BACKGROUND	10/7/99	37.20	10/28/99	14.50
BACKGROUND	10/7/99	24.80	10/28/99	21.40
BACKGROUND	10/7/99	8.28	10/28/99	11.40
BACKGROUND	10/7/99	33.10	10/28/99	14.70
BACKGROUND	10/7/99	24.80	10/28/99	14.80

From these measurements, it was determined that background did not change appreciably over the duration of each sampling period, but was appreciably different between the two sampling periods. When the direct static measurement background data is analyzed both graphically and with goodness-of-fit tests (Figure 3-1), it shows that the measurements are better represented by, or fit to, a lognormal distribution for survey unit 779-21 and a normal distribution for survey unit 779-23. A lognormal distribution is the expected condition for instrument response to alpha.

background radiation due to the naturally low alpha background count rate and the Poisson distribution associated with low level radiation counting. The direct static field measurements collected in the survey units fit the same distributions (see Section 3.1.2). The variance in the recorded background data was small and within the range expected for a gas proportional counter measuring alpha background radiation (see Appendix E for complete background data set).

Table 3-2 shows the background data summary statistics.

3.1.1.1 Background Adjustment

Because the background and survey unit sample sets were both lognormally and normally distributed, it was decided that the geometric (or lognormal) mean background value recorded over the sampling period (22.0 and 11.1 dpm/100 cm², respectively) would be used to correct the gross direct static surface contamination measurements for subsequent comparison to the applicable DCGL. In some situations, a graphical or visual distinction can be made between measurements containing background only and those with added radioactivity. For example, when elevated or contributed activity is present, a graphical distinction can be clearly seen between the population of measurements containing only background response and those containing elevated or contributed activity. This is not typically the case with alpha radioactivity. No graphic distinction between measurement results attributable to background and those with activity in excess of background is clearly discernable with this data set.

Calculational methods are needed to assess the surface activity above background that could be distinguished with statistical significance from background. As discussed earlier, the geometric mean instrument background measurements over the field sampling period were 22.0 and 11.1 dpm/100 cm², respectively. With the E-600 instruments used, the background radiation influence on the instrument's readings was processed with efficiency corrections and probe size corrections such that background measurements and sample measurements alike read out in units of dpm/100 cm². In order to calculate the statistically significant surface activity which could be distinguished from background (*a posteriori* MDA), it was necessary to convert the background measurement units from dpm/100 cm² to units of counts per minute (cpm). In this case, the more conservative metric, the arithmetic mean, was chosen to calculate the detection sensitivity achieved to prevent overstating the actual sensitivity achieved. The converted mean background count rates for the sampling periods are 4.87 and 2.37 cpm, respectively (Table 3-3). Using the

actual instrument field measurement parameters, a calculation of the actual field measurement MDA can be determined by solving Equations 3-1, 3-2, and 3-3.

Table 3-3. Static Surface Contamination Measurement MDA Parameters

Parameter		Value Used		Remarks
		779-21	779-23	
C _b	Background Counts	7.30	3.55	Values used are 24.192 and 12.158 dpm/100 cm ² converted to units of counts (cpm × T _s)
T _s	Sample count time (in minutes)	1.5		Count time programmed into the calibrated instrument specifically for this sampling event
A _p	Probe size	100		cm ²
ε _T	Instrument system efficiency in counts/disintegration	0.20	0.195	Actual efficiency for the individual probe is programmed into the memory chip of the probes' smart pack and for the two probes used was 20.76% and 19.49%. These represent effectively equivalent measures of efficiency and probe performance.

The following calculations define the *a posteriori* MDA.

$$MDA = \frac{3 + 4.65\sqrt{C_b}}{T_s \times \frac{A_p}{100cm^2} \times \epsilon_T} \tag{3-1}$$

Where: MDA = the minimum surface activity concentration above background radioactivity (in dpm/100 cm²) that can be detected with 95 percent confidence.

- C_b = the total number of background counts over the sample count period (T_s).
- T_s = sample count time (in minutes).
- A_p = probe size (in cm²).
- ε_T = counting system efficiency in count/disintegration.

$$MDA = \frac{3 + 4.65\sqrt{7.30}}{1.5 \times 1 \times 0.20} \qquad MDA = \frac{3 + 4.65\sqrt{3.55}}{1.5 \times 1 \times 0.195} \tag{3-2}$$

$$MDA = \frac{15.56}{0.302} = 52 \text{ dpm}/100 \text{ cm}^2 \qquad MDA = \frac{11.76}{0.293} = 40 \text{ dpm}/100 \text{ cm}^2 \tag{3-3}$$

Therefore the "gross" field instrument readings, using the procedures identified in the Building 779 Cluster IV SAP, which can be distinguished as different from background (the adjusted gross MDA) are:

$$24 + 52 = 76 \text{ dpm}/100 \text{ cm}^2 \qquad 12 + 40 = 52 \text{ dpm}/100 \text{ cm}^2 \tag{3-4}$$

Having identified the *a posteriori* MDA for the field sampling measurements and the adjusted gross MDAs, a simple sort of the gross field measurement data points was performed to identify those measurements from survey unit 779-21 and 779-23 which were greater than 76 dpm/100 cm² and 52 dpm/100 cm², respectively. Those locations with gross surface activity

32

greater than the adjusted gross MDA are credited as positive indicators of added radioactivity, while those less than the adjusted gross MDA are statistically indistinguishable from background values.

Rather than correct each individual measurement for background, the gross measurement data set was statistically analyzed. The data set was treated as lognormally distributed, the overall best fit for the data set collected. This treatment conforms to standard EPA methodology for data evaluation statistics, and generally yields conservative estimates of the upper confidence intervals and percentiles values. To correct for the instrument's response to background, the geometric mean background, 22.0 and 11.1 dpm/100 cm², respectively, was subtracted from the geometric mean of the total surface activity measured by surface emission data set of interest. When comparisons of other metrics (e.g., the median) are provided for information, the comparable background metric is also used to correct the reading for background radiation influence. For example, when the net (background corrected) *median* direct static surface contamination metric is reported, the *median* value of the background data set has been subtracted from the *median* value of the gross direct static surface contamination measurement data set.

3.1.2 Field Measurement Data

Direct static measurements were made at the 29 selected sample locations in each of the two survey units (779-21 and 779-23). Figure 2-2 shows the layout of both survey units and the sample locations selected in accordance with the sample allocation protocol identified in the IV SAP (DOE 1999a). They were made prior to collection of a smear sample at the location and prior to collecting a surface media sample. In this way, the "total" surface deposited activity emission rate, whether from fixed or removable radioactivity, was accounted for. In all, 33 direct static surface measurements were made in each survey unit prior to collecting surface samples. Four of these, in each survey unit, were replicate measurements collected as part of the overall QA/QC as described in the SAP. For data reduction purposes, the arithmetic mean of a replicate measurement and the corresponding initial measurement was used as the reported value for a specific sample location at which a replicate measurement was made. Consequently, there are a total of 29 data points (Table 3-4) for each survey unit included in the overall characterization of the building's mean residual surface contamination level as measured by direct surface emission. Further information about the duplicate samples and the assurance of precision and variability are presented in Sections 6.0 and 7.0.

A number of statistical tests of the data were performed to assess the data sets. A key test of the data set is for goodness-of-fit. It is important because it identifies the underlying distribution of the data set and permits the analyst as well as the decision makers and risk managers to compare appropriate metrics calculated from the data. The W-test was used to measure the relative goodness of the fit of the observed data distribution to both the normal and lognormal standard distributions. Other distributions were not entertained for this data set since the data were expected to be either normally or lognormally distributed (based on knowledge of radioactivity distribution in the environment and in background) and because the probability plots and histograms generated gave no evidence that other than normal or lognormal distributions might be present. For the direct static measurement data set, the W-test identified the lognormal distribution as the best fit for survey unit 779-21 and the normal distribution for survey unit 779-23. The data evaluation statistics are provided in Figure 3-2. Table 3-5 summarizes the

direct surface measurement data, uncorrected for background, collected in survey units 779-21 and 779-23.

LCL (lognormal "t", b=0.05)	15.18	12.60

From Table 3-5 and the data evaluation and summary statistics, it is evident that for survey unit 779-21, approximately 76 percent of all the measurements are at or below the geometric mean background value of 22.0 dpm/100 cm² and the critical detection level of 22 dpm/100 cm². Those that exceed the critical level give some evidence of activity above background but not enough to be quantified with certainty. All measurements except one are below the adjusted gross MDA (MDA_{Gross}) of 76 dpm/100 cm² for the field measurement process. The maximum value of 78.6 dpm/100 cm² was measured on the cinder block wall inside the elevator shaft in room 144 of survey unit 779-17 at sample location IVP0000227.

Only 34 percent of the measurements taken in survey unit 779-23 are at or below the geometric mean background value of 11.1 dpm/100 cm² yet 93 percent are below the critical detection level of 22 dpm/100 cm². Once again, those that exceed the critical level give some evidence of activity above background but not enough to be quantified with certainty. All measurements are below the MDA_{Gross} of 52 dpm/100 cm² for the field measurement process. The maximum value of 24.7 dpm/100 cm² was measured on the sealant covered concrete north wall of survey unit 779-23 at sample location IVP0000241.

The test of DCGL_w for total surface contamination concentration as measured by direct surface emission is the mean (the geometric mean in the case of unit 779-21 since this data set is determined to be lognormally distributed and the arithmetic mean in the case of unit 779-23 since this data set is determined to be normally distributed) of the data sets. Section 4.0 provides detailed analysis of the data set in comparison to the applicable DCGL values.

3.1.2.1 Post Surface Media Sampling Measurements

Follow-up direct static measurements were made after each surface media sample was collected in an effort to assure that all of the contaminant which might have been present beneath the immediate surface was removed by the physical sampling process. This measurement was necessary to validate the assumption that any contaminant that may have been deposited beneath a paint layer or embedded in the porous substrate was limited to only shallow deposition and would be collected and measured by the surface media sampling. Evidence of elevated radioactivity by direct measurement after a thin surface veneer had been removed might call into question the validity of that assumption, requiring further investigation. The results, however, are not considered in the data set used to evaluate compliance with the DCGL_w for total surface

contamination as measured by direct surface emission. Nonetheless, the post surface media sampling measurements are considered important since they might detect radioactivity that is potentially "hidden" from detection by direct surface emission measurements made before removal of the surface coating or veneer.

A total of 18 (14 from unit 779-21 and 4 from unit 779-23) surface media samples (Table 3-6) were collected from sample locations which met the stringent surface media sample inclusion criteria (DOE 1999a). A total of 19 direct static surface measurements were made at the 18 surface media sample locations subsequent to collecting surface samples. One of these was a replicate measurement collected as part of the overall QA/QC as described in the SAP. Where the replicate measurement was made, the arithmetic mean of the replicate measurement and the corresponding initial measurement was used as the reported value for that specific sample location.

Table 3-6. Post Surface Media Sample Direct Static Surface Measurements

Survey Unit 779-21		Survey Unit 779-23		Instrument Operating Mode	Channel Selected	Background Compensation Mode

IVP0000211	20.70			Scaler	Alpha	Gross
IVP0000212	33.10			Scaler	Alpha	Gross
IVP0000221	33.10			Scaler	Alpha	Gross
IVP0000222	12.40			Scaler	Alpha	Gross
IVP0000223	20.70			Scaler	Alpha	Gross
IVP0000226	20.70			Scaler	Alpha	Gross
IVP0000227	24.80			Scaler	Alpha	Gross
IVP0000229	4.14			Scaler	Alpha	Gross

Again, a number of statistical tests of the data were performed to assess the data set. The W-test was used to measure the relative goodness of the fit of the observed data distribution. The W-test and histogram showed the survey units 779-21 and 779-23 data sets to be normally distributed. The data evaluation statistics are provided in Figure 3-3. Table 3-7 summarizes the post surface media sampling direct surface measurement data, uncorrected for background, collected in survey unit 779-21 and 779-23.

The most telling presentation of the post surface media sampling surface measurements is a side by side comparison of the data set summary statistics with the summary statistics from the direct surface measurements made prior to sampling and the instrument background data collected during the sampling process. Table 3-8 and Table 3-9 compares units 779-21 and 779-23 summary statistics from each of these three data sets.

UCL (lognormal "t", a=0.05)	25.84	34.04	29.33
LCL (lognormal "t", b=0.05)	15.18	15.45	20.39

From the data evaluation and summary statistics, it is evident that the post surface media sampling direct static measurements for survey unit 779-21 show slightly higher activity than those collected prior to sampling. However, they are slightly lower than the instrument background measurements made over the sampling period. The maximum value of 33.1 dpm/100 cm² was measured at sample locations IVP0000204, IVP0000212, and IVP0000221.

LCL (normal "t", b=0.05)	12.65	0.65	10.23

From the data evaluation and summary statistics, it is evident that the post surface media sampling direct static measurements for survey unit 779-23 show slightly higher activity than those collected prior to sampling and are slightly higher than the instrument background measurements made over the sampling period. The maximum value of 30.9 dpm/100 cm² was measured at sample location IVP0000236.

The fact that approximately half the survey results from both units yielded higher direct static measurements of activity once the paint layer had been removed and that the corresponding surface media sample yielded no appreciable measure of radioactivity tends to support the possibility that the building materials have a measurable concentration of naturally occurring radionuclides¹. For sample locations requiring media sampling, both the pre- and post-surface media sampling direct static measurement data set are presented side-by-side in Table 3-10.

3.2 Laboratory Measurements

The GJO Analytical Laboratory was used to assay all smear and surface media samples collected for independent verification from survey units 779-21 and 779-23. The GJO Analytical Laboratory was selected because of its method capabilities, quality program, autonomy, and ability to meet the detection limits specified in the SAP (DOE 1999a). In each case, the laboratory met or exceeded the contract required detection limit specified in the SAP. Results of samples analyzed are summarized in the following sections below.

¹Although indications point to the possibility of measurable concentrations of naturally occurring radionuclides, particularly in the concrete materials used in the building construction, no credit is taken by attempting to subtract these from the measured values in the building. Instead, all radioactivity measured (other than the instrument background) is assumed to be DOE contributed values and is compared against the applicable DCGL to determine compliance with the DQOs.

3.2.1 Smear Samples

Smear samples were collected at each of the 29 designated sample locations from each survey unit. Smear samples were collected following the initial direct static surface measurement by wiping the surface with an absorbent smear filter media using moderate pressure. The smears were packaged and delivered to the GJO Analytical Laboratory for counting. The 29 smear samples from each survey unit were submitted to the GJO Analytical Laboratory along with two blank and six "spiked" QC smears on October 28, 1999, for analysis. Table 3-11 is provided to aid the reader to keep the sample identification numbers straight. Results and conclusions relative to the QC smear samples are provided in Section 6.0 of this report.

With the exception of the spiked QC samples submitted, the analytical results showed no measurable radioactivity indicating that there is very little likelihood that the DCGL_w for removable surface contamination might be exceeded in the survey unit. Since every sample result was below the detection limit for the analysis (MDA), no statistical inferences can be made for the data set. However, since the method detection limit was significantly below the DCGL_w for removable alpha radioactivity, and each smear sample was shown to have activity less than the detection limit, statistical treatment of the data set is not necessary in order to measure compliance. Table 3-12 summarizes the pertinent information gleaned from the complete analytical report (Requisition #16821). The entire analytical report is provided in Appendix C.

3.2.2 Surface Media Samples

Surface media samples were collected at each sample location when either of two conditions was satisfied (DOE 1999a). First, a sample was collected at each location where a surface coating or residue, such as paint, was present on the selected surface. Second, a sample was collected at each location where the direct static surface measurement exceeded L_c , 22 dpm/100 cm², indicating the possible presence of measurable DOE added radioactivity. In all, 18 (14 from unit 779-21 and 4 from unit 779-23) surface media samples were collected; 18 of the 58 designated sample locations having met one or both conditions.

In order to achieve the required detection sensitivity and to distinguish between transuranic and uranium series radionuclides, alpha spectroscopy analysis was chosen to assay the surface media samples. Distinction between transuranic and uranium series nuclides is important because radionuclide series specific DCGLs were established for the surface media samples. Sample masses ranged from approximately 5 to 24 grams and were collected over a 100 cm² surface area. The laboratory analyzed each sample for the following radionuclide sets:

- Transuranic Series Isotopes Pu-238, Pu-239/240, and Am-241
- Uranium Series Isotopes U-234, U-235, and U-238

In spectrometric analysis, each isotope has its own counting statistics and detection limit. Many of the sample measurements resulted in one or more of the isotope specific values below the detection limit. When this occurred, a value equal to one half of the sample specific detection limit was used to calculate the total radionuclide series activity. Collated data has been derived from the complete analytical report (Requisition #16822) and presented in Table 3-13. The entire analytical report is provided in Appendix C.

From summary data presented in Table 3-13, several features are apparent:

- Isotopic assay of the contaminants found on and beneath painted and coated surfaces in Annex A indicate the persistent presence of uranium series radionuclides. Each of the 18 samples collected showed detectable concentrations of the two uranium isotopes found most abundantly in nature, U-234 and U-238. This is indicative of the presence of background contributions of these nuclides and is consistent with the background contributions expected in concrete and cinder block materials (NRC 1997).
- Only one sample, IVP000227, from among the 18 collected showed the clear presence of transuranic radioactivity. This sample was collected from inside the elevator shaft in the southwest portion of the survey unit where the highest direct measurement was recorded (78.6 dpm/100 cm²). The direct static measurement taken after the media sample was taken (24.8 dpm/100 cm²) indicates the contamination was on the surface of the cinder block and removed with the media sampling. The Contractor had earlier identified radioactive contamination in the shaft and performed a decontamination process to remove it to below the applicable DCGL value. Every other sample result had one or more of the transuranic nuclides of interest at concentrations below the detection limit.

Shaded cells indicate values below the detection limit. The reported value is the sample-specific MDA.

46

- The detection limit for a given isotope varied for each sample. This is due to the variation in the total sample mass collected. The laboratory was limited by the mass of sample that could efficiently be processed to extract the nuclides of interest. As a result, the laboratory fractionated a relatively consistent aliquot of the total mass submitted to actually perform the analysis. The larger the sample collected and submitted, the smaller the fraction represented by the aliquot. Thus, the detection limit increased (got poorer) as the total mass collected increased. In each case, however, actual field sampling procedure collected a sample from a 100 cm² area until the entire surface had been stripped of the paint layer or surface veneer.
- The one sample which indicated the presence of transuranic activity severely skews the surface media samples for transuranics. This skewness likely results in very conservative estimates of the overall residual transuranic activity in survey unit 779-21.

Surface media sample data evaluation statistics for each survey unit is presented for the uranium series, the transuranic series and the transuranic series excluding sample #263358 in Figures 3-4, 3-5, and 3-6, respectively. For information purposes, the transuranic series data summary statistics have been presented with and without the sample #263358 collected at IVP0000227. Table 3-14 presents the summary statistics for the surface media sample data set, with the transuranic and uranium series nuclides presented as independent subsets.

4.0 Analysis of Sample Plan Results for Compliance

In accordance with MARSSIM and other EPA guidance (EPA 1997) (EPA 1993), the Building 779 Cluster IV SAP identified the decision rules which provide the basis for independently verifying and assessing the RFETS Contractor's conclusions and recommendations for risk management actions in Building 779 (DOE 1999a). To accomplish this objective, the IVC was tasked with performing independent measurements of a representative fraction of the Contractor's survey, such that a statistically valid, yet independent conclusion could be drawn. In order to obtain a data set robust enough to allow statistically valid comparisons with the decision rules, the IVC selected and sampled two of the nine designated survey units in Annex A or two of 41 designated survey units in Building 779. The first decision rule supports this decision objective. The IVC was also tasked with reviewing and verifying the Contractor's Closeout Radiological Survey Report and its conclusions. Since the Contractor's decision basis is applied independently to each survey unit, a sampling and statistical test with power comparable to that used by the Contractor was needed in order to compare with the conclusions reached by the Contractor. The second decision rule supports this objective. The decision rules which define compliance for the independent verification of the Building 779 Cluster surveys are specified in the IV SAP (DOE 1999a) and were reviewed by the EPA and approved by DOE and CDPHE. The IVC's SAP specifies the following two decision rules:

If the independent verification survey concludes that, in the selected survey unit(s), the mean (or median) removable surface contamination concentration is below 20 dpm/100 cm² gross alpha activity, and the mean (or median) total alpha surface contamination concentration as measured by direct surface emission is below 100 dpm/100 cm², and the maximum total alpha surface contamination concentration as measured by direct surface emission is below 300 dpm/100 cm², and the mean (or median) contamination concentration on and beneath a surface with a surface coating as measured by collection and analysis of a surface media sample is below 100 dpm/100 cm² for all transuranic nuclides combined and below 5,000 dpm/100 cm² for all uranium series nuclides combined, then conclude that the survey unit meets the release criterion.

If the IVC survey conclusion disagrees with the Contractor's final status survey conclusion, then refute the Contractor's conclusion for the survey unit and consult with the DOE-RFFO contact for direction on discrepancy resolution.

Demonstrating compliance with the decision rules for independent verification provides DOE with assurance that a substantial and credible case exists for releasing the buildings from further radioactive contamination controls during demolition or disposal.

The first decision rule forms the basis for the five DCGLs, the benchmarks against which measured values are compared to determine compliance. Each component of the decision rule can be reduced to a specific DCGL. The DCGLs for Annex A Closeout Radiological Survey are:

- 20 dpm/100 cm² for removable alpha surface contamination
- 100 dpm/100 cm² (mean or median) total alpha surface contamination as measured by direct surface emission

- *300 dpm/100 cm² (maximum) total alpha surface contamination as measured by direct surface emission*
- *100 dpm/100 cm² (mean or median) total transuranic surface contamination on and beneath a surface with a surface coating as measured by collection and analysis of a surface media sample*
- *5,000 dpm/100 cm² (mean or median) total uranium series surface contamination on and beneath a surface with a surface coating as measured by collection and analysis of a surface media sample*

4.1 Survey and Sampling Results Compared to the DCGLs

The following sections address each component of the sampling performed and compare the results to the applicable DCGLs. While the data sets collected by the IVC have been shown to best fit both normal and lognormal distributions, the DCGL_w values, as stated by the RFETS Contractor (RMRS 1999a), do not specify whether the compliance benchmark assumes the arithmetic mean or some other estimate of central tendency appropriate to the distribution. For example, in the case of lognormally distributed data, the lognormal average (i.e., geometric mean) is a more appropriate indicator of the central tendency. When the distribution is not well known or abnormally skewed, the median value generally provides a good estimate of the central tendency for the data set. For comparison purposes in this report, the arithmetic (or normal) mean, the lognormal mean, and the median value are provided for each data set along with the maximum values observed. These provide the risk managers and decision maker with the range of plausible values that might be encountered and considerable evidence, regardless of the underlying distribution, for comparison with the DCGL benchmarks.

4.1.1 Direct Static Surface Measurements

Table 4-1 presents the gross direct static surface measurement results obtained in survey units 779-21 and 779-23. In this table, no correction for instrument background has been made in order to provide the risk managers and decision makers with the information needed to compare corrected and uncorrected results in the survey unit and correlate the measured residual radioactivity in the survey unit not only with the DCGL but also with the comparable measure of background.

Table 4-2 compares the background adjusted survey unit measurement results to the applicable DCGL. The background adjustment for direct static measurements is made by simply subtracting the central tendency estimate of the background measurements made over the sampling period from the comparable central tendency estimate of the gross, or unadjusted values collected and recorded in the field (see Section 3.1 for detailed discussion of background correction methods employed).

Table 4-1. Comparison of Direct Static Survey Measurements to Applicable DCGLs

Annex A, Survey Units 779-21 and 779-23 Unadjusted (Gross) Measurements (dpm/100 cm ²)												
DCGL Value (Total Surface Contamination by direct surface emission)	Arithmetic Mean		Lognormal Geometric Mean		Median		Arithmetic UCL ₉₅		Lognormal UCL ₉₅		Maximum	
	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23
100 dpm/100 cm ²	19.36	14.87	15.51	13.44	16.60	14.10	24.86	17.10	25.84	18.52		
300 dpm/100 cm ²											78.6	24.7

Table 4-2. Comparison of Background Adjusted Direct Static Survey Results to Applicable DCGLs

Annex A, Survey Units 779-21 and 779-23 Background Adjusted (Net) Measurements ^a (dpm/100 cm ²)												
DCGL Value (Total Surface Contamination by direct surface emission)	Arithmetic Mean		Lognormal Geometric Mean		Median		Arithmetic UCL ₉₅		Lognormal UCL ₉₅		Maximum	
	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23
100 dpm/100 cm ²	-4.8 ^b	2.27 ^b	-6.5 ^b	2.33 ^b	-8.2 ^b	2.4 ^b	-3.3 ^b	3.01 ^b	-3.5 ^b	3.76 ^b		
300 dpm/100 cm ²											37.2 ^b	3.2 ^b

^aBackground corrected values are provided for information. They are well below the DCGL values and just slightly above background.

^bThe following background values were used to adjust the direct static measurement values:

	779-21	779-23
Arithmetic Mean =	24.2	12.16
Lognormal Geometric Mean =	22.0	11.11
Median =	24.8	11.70
Arithmetic UCL =	28.2	14.09
Lognormal UCL =	29.3	14.76
Maximum =	41.4	21.50

From the above data, it is evident that the surface contamination as measured by direct surface emission from the building surfaces in survey units 779-21 and 779-23 is well below the DCGL_w. The IVC did not employ a scanning survey method in the independent verification sampling plan. Rather, the IVC has evaluated the scanning data collected by the Contractor to determine if the data supports the conclusions reached by the Contractor with respect to the DCGL_{EMC}. However, it is interesting to note the maximum concentrations measured using direct static methods as they compare to the DCGL_{EMC}. The maximum value measured in survey units 779-21 and 779-23 are substantially below the DCGL_{EMC} and the background adjusted mean concentrations are significantly less. The independent verification data cannot exclude the possibility that localized concentrations of surface contamination might exist above the DCGL_{EMC} value. But, given the number of measurements made, knowledge about the nature of the distribution of the data, and the large differences between the data metrics and the DCGL_{EMC}, it can be inferred that the likelihood of encountering even moderately sized areas with concentrations exceeding the DCGL_{EMC} is small.

4.1.2 Smear Samples for Removable Surface Contamination

Smear samples are not subject to the influence of background radiation at the site, but the radiation counting instruments used to assay these samples are subject to background radiation levels at the counting laboratory and have inherent instrument backgrounds which are corrected by the laboratory processing the samples. Since the background corrections performed are not relevant to the conditions encountered in Annex A, only the background adjusted values are provided here in Table 4-3. The raw counting data can be referenced in the analytical laboratory report for the smear samples contained in Appendix C.

Table 4-3. Comparison of Smear Sample Results to Applicable DCGL_w.

Annex A, Survey Units 779-21 and 779-23 Smear Sample Results (dpm/100 cm ²)												
DCGL Value	Arithmetic Mean		Lognormal Geometric Mean		Median		Arithmetic UCL ₉₅		Lognormal UCL ₉₅		Maximum	
	779-21	779-23	779-21	779-23	779-21	779-23			779-21	779-23		
20 dpm/100 cm ² Removable Surface Contamination	<5.33	<5.33	<5.33	<5.33	<5.33	<5.33	NA	NA	<5.33	<5.33		
All 58 smear samples yielded total alpha activity below the detection limit for the analysis. The method detection limit is presented for comparative information.												

From the above data, it is evident that the removable surface contamination, as measured by smear sampling of the surfaces in survey units 779-21 and 779-23, is well below the DCGL.

4.1.3 Surface Media Samples

As with smear samples, surface media samples are not subject to the influence of background radiation at the site, but have been corrected for the background present at the laboratory by the laboratory processing the samples. Again, since the background corrections performed are not relevant to the conditions encountered in the Annex A, only the background adjusted values are provided here in Table 4-4. The raw counting data can be referenced in the analytical laboratory report for the surface media samples contained in Appendix C.

Table 4-4. Comparison of Surface Media Sample Results to Applicable DCGLs

Annex A, Survey Units 779-21 and 779-23 Surface Media Sample Results (dpm/100 cm ²)												
DCGL Value	Arithmetic Mean		Lognormal Geometric Mean		Median		Arithmetic UCL ₉₅		Lognormal UCL ₉₅		Maximum	
	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23	779-21	779-23
100 dpm/100 cm ² Total Transuranic Activity by surface media sample	4.8	1.3	2.6	1.2	2.7	1.3	9.8	1.9	7.2	2.3	34.4	1.7
5,000 dpm/100 cm ² Total Uranium Series Activity by surface media sample	68.5	21.7	52.5	17.8	70.0	13.9	86.5	50.2	191.1	66.4	140.8	48.48

56

From the above data, it is notable that the maximum total transuranic activity contained on and in a thin veneer beneath the surface sampled is significantly below the allowable *mean* value. This is notable in that, as the maximum total transuranic activity collected within the entire survey unit, this measurement represents less than 50 percent of the allowable mean value. This data indicates that it is extremely unlikely that the building contains any added radioactivity and is considered safe for unrestricted release.

In fact, most of the samples measured for transuranic activity resulted in measured concentrations below the method detection limit for the analysis. Some of the transuranic activity reported is attributed to americium-241 (Am-241) owing to interference in the energy window for Am-241 rather than americium activity. (See Appendix C for the method blank data indicating the activity showing up as Am-241 even when no americium is present.)

The total uranium series activity was consistently measured at concentrations exceeding the method detection limit even though the concentrations measured were consistently significantly below the applicable DCGL. The presence of detectable concentrations of uranium series nuclides does not, however, necessarily indicate that the activity is DOE contributed activity. In fact, isotopic ratios present in the samples support the position that the uranium series activity is naturally occurring radioactivity present in the construction materials from which the building was made. Nonetheless, because a decision was made during sampling plan design to avoid the need to make reference survey unit comparisons in order to statistically verify this assumption, all of this activity is herein assumed to be DOE contributed and is compared directly to the applicable DCGL. Even with this conservative assumption, it is clear that the residual uranium series activity on and in a thin veneer beneath the surface sampled is well below the DCGL.

4.2 Summary of Field Sampling Data

As evidenced above, each metric—the arithmetic average, logarithmic average, their respective 95 percent upper confidence limit (UCL_{95}) estimates and the median value—is well below the applicable $DCGL_W$ concentration value. Moreover, the maximum value for each data set is well below not only the applicable $DCGL_{EMC}$ but also below the $DCGL_W$. Based on the direct static measurements, removable smears sample results, and surface media sample results collected in the survey units selected for independent verification (779-21 and 779-23) in Annex A, there is no evidence of radiological surface contamination levels exceeding the selected DCGLs.

Thus, the first of the tests of the DQO decision rule—the *residual radioactivity must not exceed the applicable DCGLs*—has been verified.

End of current text

54

5.0 Graphic Presentations of the Survey and Sampling Results

Graphics are a powerful and valuable tool used in reviewing the data collected. Graphic presentations—Normal Probability, Log Probability, and Probability Density Function Plots—have already been provided in Section 3.0 in support of the determination of the underlying distribution of each data set. In addition to these graphical treatments of each of the data sets collected, additional pictorial presentations are provided in Section 6.0 to assist the risk manager and decision maker in evaluating the data. Each form of graphic presentation provides a unique perspective or advantage in the data evaluation process.

5.1 Posting Plots—Spatial Contamination Distribution Graphics

Posting plots are presented for visualizing the spatial contaminant distribution within the survey unit sampled and surveyed by the IVC. Trends in spatial distribution become evident when data is plotted in this manner. The results of each data set, normalized to units of dpm/100 cm², are superimposed over the building surfaces. The walls and ceilings in the building are “unfolded” to form a contiguous surface segment, as when a cardboard box is unfolded and laid flat. Three posting plots are provided for each survey unit. One plot (Figure 5-1) displays the 29 direct static surface contamination measurements made in survey units 779-21 and 779-23. The data used to generate these posting plots are “gross” measurements (not corrected for the mean background of 22.0 and 11.1 dpm/100 cm², respectively) to avoid negative numbers. Figures 5-2 and 5-3 display the surface media sample results from both survey units for transuranic and uranium series activities, respectively.

The posting plots confirm that no substantial spatial trends in residual activity are present.

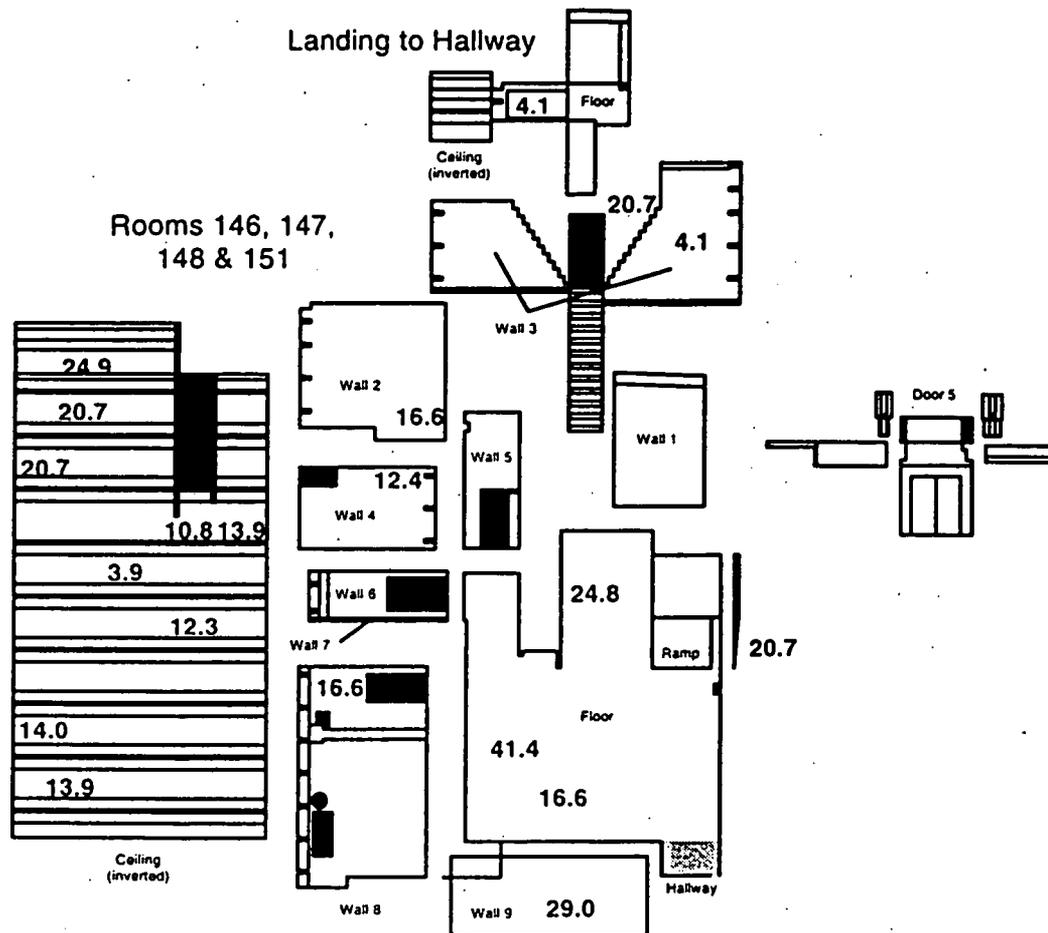

5.2 Histograms—Concentration Distribution Graphics

One of the oldest methods used for analyzing data set distributions is the histogram (or frequency plot). The data are divided into units, or bins, representing increments of activity. The data set is then sorted into these bins and the number of data points occurring in each bin (the frequency) is counted and then plotted using a bar graph. This presentation is designed to provide for visual means of assessing the symmetry and variability of the data set. When constructed correctly, the histogram will indicate if the data are skewed and will show the direction of skewness (EPA 1998). Figures 5-4 and 5-5 display the histograms (technically frequency plots) for the background and direct static surface measurement respectively from each survey unit. Figures 5-6, 5-7, and 5-8 display the post-surface media sampling direct static surface measurement, surface media samples for transuranics, and surface media samples for uranium data sets from survey unit 779-21. The display of these data sets for survey unit 779-23 is not presented since only four media samples were taken.

All but two of the histograms provide evidence of a relatively symmetric or normal distribution in the data set with most data clustered around a non-discrete central concentration, which is substantially below the applicable DCGL. Two show evidence of a slightly left shifted skewness, which is typical of environmental radioactivity data. The histograms support the general conclusion that the data distributions of most data sets are best estimated by the normal distribution.

5.3 High-Low Graphs—Data Variability Graphics

A key element in the evaluation of the sampling and survey data is the variation within the data set. As the data variability increases, the ability of the risk manager to confidently make decisions about the true state of radiological contamination in the survey unit or building in relation to the applicable DCGL and null hypothesis decreases. When variability is small (or excessively large) relative to the difference between the mean and the DCGL, the risk managers can be confident in the decisions made using the data set provided. When evaluating data variability, it is important to know, first, that the data set contains a sufficiently large sample population (number of measurements). Retrospective power curves, demonstrating the “power” of the sign test to reject the null hypothesis with the actual sample size collected, are presented in Section 8.0. High-Low graphs are simple presentations showing the range between the upper and lower 95 percent confidence intervals about the geometric mean. Figures 5-9, 5-10, and 5-11 depict the variability observed in each type of data analyzed.

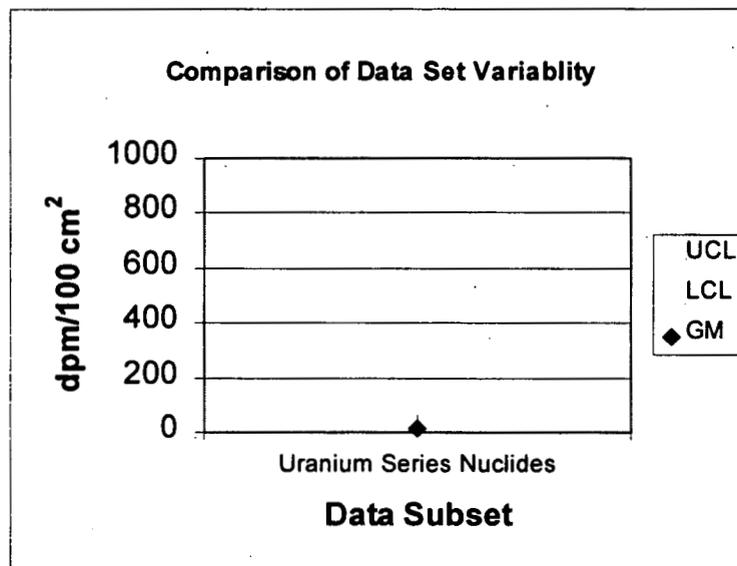

Figure 5-11 (continued): High-Low Graphs—Surface Media Samples, Uranium Series Activity, 779-23

The pattern of a comparatively low central tendency, and small measure of data variability in each of the data sets presented provide substantial evidence that the estimates of the true mean residual radioactive concentrations presented are below the DCGLs. No DCGL is included in the 95 percent confidence intervals about the mean. The lack of significant variability in any of the data sets is also indicative of a lack of discretely distributed activity (supporting the conclusions of the posting plots above) and excellent precision in the analytical methods employed in the sampling and measurements processes. By presenting the three data sets made with the same instruments and procedures (background, direct static measurements, and post-surface media sampling direct static measurements), it is also evident that they report essentially equivalent

measures of activity. In other words, the best estimates of surface activity as measured by direct surface emission are statistically indistinguishable from background. The larger range between the upper and lower 95 percent confidence intervals about the arithmetic mean displayed in the Post-Media Sampling data set for survey unit 779-23 (Figure 5-9) is the result of an extremely small data set.

Other visual presentations of the data are possible and may have been indicated if the data sets available were less robust than they actually are. However, the graphic treatment of the data presented here and in other sections is sufficient to enable the risk managers and decision maker to make confident determinations respecting the data.

6.0 Quality Control Sampling Results and Analysis

An important aspect of any sampling plan is the effort made to assure the quality of data collected. The independent verification process as a whole is a quality assurance method in itself. Thus, it was critical to assure the quality of all of the independent verification data through quality checks and controls, calibrations, training, and qualification of laboratories and services used. The objective of independent verification for the Building 779 Cluster final status radiological surveys, added an element of quality assurance to the design of the sampling evolution. In addition to designing quality checks and controls into the independent verification sampling, the IVC provided for QC checks to assess the quality of the Contractor's data.

The IV SAP distinguished these two principal QC objectives in the design of the sampling plan. Stage I QC sampling was designed to assess the quality of the data collected by the Contractor. Stage II QC sampling was designed to assess the quality of the data collected by the IVC. In each case where QC samples were used, either for Stage I or Stage II sampling, the samples were maintained under chain-of-custody control from the time they were prepared until they were introduced to either the Contractor's or IVC's sample batch. Tamper seals and locked storage were employed when samples were not in the physical custody of the IVC's Field Team Leader.

The IV SAP specifies QC sampling to be performed over the duration of the Final Status Survey performance for all survey units in the Building 779 Cluster rather than for each specific building. This report, specific to Annex A, does not contain every element of QC data planned for the cluster of buildings as a whole. The costs associated with implementing separate QC sampling for each building in the 779 Cluster was determined to be prohibitive and unnecessary. Instead, a cumulative assessment and presentation of QC data will be presented with each successive Independent Verification Report of the Contractor's Final Status Survey.

This section of the report presents the QC data collected and measures employed to assure that quality objectives in the design of the sampling plan were achieved. Section 7.0 assesses the overall data quality against the published or industry accepted data quality indicators.

6.1 Stage I—Independent Quality Control of the Contractor's Sampling

6.1.1 Smear Samples

The IVC provided smear samples to the Contractor for measurement and analysis by the Contractor's selected instrumentation and methods. An unopened package of smear sample media was obtained from the Contractor prior to the start of the independent verification of Annex A. The IVC assigned a series of these as "blanks" and spiked a second series of smears with three different concentrations of an alpha emitting transuranic nuclide (one which is part of the nuclide mix identified as a contaminant of concern for the 779 Cluster).

The spikes were not certified as containing traceable concentrations of the nuclide added. Thus, the spikes do not provide a measure of accuracy directly. Accuracy is established for the instrument measuring the activity on the smears by the RFETS (or contract laboratory, if used) calibration and analysis procedures. Instead, the spikes serve to provide a comparison between the results achieved by the Contractor and those achieved by the IVC.

The blank smears test the ability of the counting instrument used to distinguish between background and added activity as well as the ability of the counting technician and sample handling process to prevent cross-contamination.

The IVC introduced seven blank smears and six spiked smears into the Contractor's smear sampling batch during this portion of the final status survey. The QC samples were packaged and identified exactly as the Contractor's procedure dictated. Because the Contractor used the same technician to collect and analyze the smear samples they collected, it was not possible to present a double blind set of QC samples. He would know when samples other than those he personally collected were introduced. They were presented as a single blind set of QC samples. The Contractor's counting technician was not aware of the objective of the samples, nor the fact that some were blanks and some were spikes.

The blank smears were prepared by wiping a clean, unaffected, and uncontaminated surface. Each was then packaged individually, assigned a unique QC sample number, and physically controlled to ensure custody and integrity. The spiked smears were prepared by pipetting liquid standard concentrations onto a smear filter disc.

Spiked smears were prepared with three different quantities of radioactivity to provide a range of gross alpha radioactivity concentrations over the range expected to be encountered in the Final Status Survey. This range is necessarily small and near zero for a Final Status Survey.

The QC samples provided to the Contractor were measured and reported to the IVC by the Contractor and the GJO Analytical Laboratory (Appendix F). Table 6-1 provides a crosswalk between the IVC and Contractor assigned sample numbers and presents a summary of the results obtained by the Contractor and the GJO Analytical Laboratory which establishes a cumulative cross comparison as a measure of the relative accuracy of the instruments and methods employed. To provide greater statistical power than can be achieved with just a few measurements, Table 6-1 includes the results from survey units 729-01, 779-04, 779-17, 779-21, and 779-23 for a cumulative comparison. Each subsequent report will include the results from the previously completed survey units.

From Table 6-1, it is seen that all but one of the twenty blank smears returned results indicating no detectable radioactivity or activity less than the reported MDA. As reported in the IVC Sampling and Survey Report, Building 729 (DOE 1999), sample #2C was identified by the Contractor as having 4.5 dpm/100 cm².

Each of the 21 spiked smear samples yielded measurable radioactivity. The 21 spiked activities were differentiated from one another in the Contractor's assay. Yet, sample #6C, #13C, and #16C were reported to have activity below the MDA for the method. As reported in the IVC Sampling and Survey Report, Building 729 (DOE 1999b), this might be caused by too short of a counting time (background, sample, or both) to adequately distinguish between background and low-level activity. Smear #6C and #13C were spiked to the lowest concentration of the three and were expected to return the lowest measurement of activity among the three. Likewise, the highest spiked activity returned the highest measurement of activity among the three. Another possible explanation for the lower than expected result on these smear samples is in the method used to prepare the spiked samples. As mentioned earlier, a liquid standard containing an alpha

^aSmear samples were disposed of by the Contractor before being counted by the GJO Analytical Laboratory.

The Contractor counted the smears with an Eberline model SAC-4 alpha smear counters (serial #1069, 1406, and 814). The measured background was 0.2, 0.4, and 0.3 cpm, respectively. The efficiency was established at 33.3 percent.

emitting transuranic nuclide was pipetted onto the smear and then allowed to dry. It is likely that a significant fraction of the total activity deposited migrated to a depth in the smear matrix that the activity was attenuated by the sample media itself.

6.1.2 Surface Media Samples

A total of 23 Stage I and 14 Stage II surface media QC samples have been analyzed for a cumulative comparison. Surface media QC samples were made in duplicate (one to be introduced in the Contractor's sample batch and the other in the IVC's sample batch). Before being introduced by either the Contractor or IVC, they are analyzed by the GJO Analytical Laboratory. A comparison of results between the initial count by the GJO Analytical Laboratory, the Contractor's Laboratory, and the GJO Analytical Laboratory when the QC sample was recounted when introduced with the IVC sample batch is presented in Table 6-2. The remaining twelve Stage II surface media samples will be introduced during the IV of the remaining survey units for the 779 Cluster.

6.1.3 Direct Surface Emission Measurements

The Contractor and the IVC chose to utilize the same response check source to test the response of instruments used to make direct surface emission measurements (Table 6-3). This enabled the comparison of routine instrument response checks using the same isotope, geometry, and activity. Three instrument systems were employed to make direct surface emission measurements during the Final Status Survey of Annex A. The Contractor employed a subcontractor, Millennium Services, who used a proprietary system (SCM/SIMS) developed by Shonka Research Associates to perform the scan surveys. The SCM is fundamentally a gas proportional counter and the SIMS is the survey information management software. The Contractor also used a NE Electra with a DP-6 dual phosphor scintillation probe to make direct static surface measurements for comparison with the DCGL_w. The IVC used the Eberline model E-600 multi-purpose survey instrument with a HP-100 gas proportional probe.

Table 6-3. Comparison of Response of Instruments used to Make Direct Surface Measurements

Standard Deviation	280	83	53
Coefficient of Variation	0.22	0.07	0.04

6.2 Stage II—Quality Control of the Independent Verification Sampling

Stage II QC sampling is associated specifically with the IVC's field sampling and serve to establish confidence in the independent verification sampling results rather than correlate them with the Contractor's results. Again, not every category of QC measure planned for has been completed to this point.

62

6.2.1 Smear Samples

The IVC provided smear samples to the GJO Analytical Laboratory for measurement and analysis. Smear sample media was reserved by the IVC prior to the start of the independent verification of Annex A. A series of these were assigned as "blanks" and a second series of smears was spiked with three different concentrations of an alpha emitting transuranic isotope of the nuclide mix identified as a contaminant of concern for the 779 Cluster.

As with the spikes prepared for the Contractor, the spikes were not certified as containing traceable concentrations of the nuclide added. Thus, the spikes do not provide a direct measure of accuracy. Instead, the spikes serve to provide a measure of confidence in the laboratory's ability to detect radioactivity and to establish a basis for subsequent comparison between the results achieved by the Contractor and those achieved by the IVC.

The IVC introduced two blank and six spiked smears into the smear sampling batch during the independent verification survey of survey units 779-21 and 779-23 in Annex A. The entire batch of smears was then provided to the GJO Analytical Laboratory. The QC samples were packaged and identified exactly as those samples collected in the survey unit and were not distinguishable to the analyst. Because the IVC used an independent laboratory to assay smears, and because the technician collecting the field smears was not involved with preparing, handling, or counting smears, it was possible to present the QC samples along with the field samples as a double blind set.

The blank smears were prepared by wiping a clean, unaffected, and uncontaminated surface. They were then packaged individually, assigned a unique QC sample number, and physically controlled to ensure custody and integrity. The spiked smears were prepared by pipetting liquid standard concentrations onto a smear filter disc.

Spiked smears were prepared with three different quantities of radioactivity to provide a range of gross alpha radioactivity concentrations over the range expected to be encountered in the Independent verification of the Final Status Survey. The range was, again, small and near zero.

The QC samples provided to the IVC's laboratory were measured and reported to the IVC (Appendix F). Table 6-4 provides a crosswalk between the IVC and GJO Analytical Laboratory assigned sample numbers and presents a summary of the cumulative results obtained by the laboratory.

From Table 6-4 it is seen that each blank smear returned results indicating no detectable radioactivity in excess of the method detection limit. Each spiked smear sample yielded measurable radioactivity. They were differentiated from one another and the lowest result corresponded to the smear with the lowest spiked concentration while the highest result corresponded to the smear with the highest spiked concentration.

Again, no statement can be made about the accuracy of the results reported by the IVC's laboratory subcontractor but results were in line with those expected. The fact that the GJO Analytical Laboratory apparently used longer counting times than did the Contractor when measuring smears adds weight to the possibility that insufficient counting time may be at the root of the disparity in the results on QC smear samples reported by the Contractor.

^aThe analytical report presented results in pCi per sample. The results have been converted to dpm for presentation in this table. Since the smears were collected over a 100 cm² area, the results in dpm are equivalent to dpm/100 cm².

^bThe laboratory formally reported values as less than the detection limit (<MDA) but provided the raw supporting data in the complete analytical report. These blank QC samples resulted in a negative net count rate.

The GJO Analytical Laboratory counted the smears with a Canberra low background automated scaler, model 2404 smear counter. The measured background was 0.097 cpm over 60 minutes. Sample count time was 6 minutes. The alpha efficiency was established at 21.39 percent.

As reported in the IVC Sampling and Survey Report, Building 729 (DOE 1999b) several smear samples submitted to the GJO Analytical Laboratory and to the Contractor were disposed of by the laboratories before they could be collected and provided to the other laboratory for a cross comparison of laboratory measurements. To remedy this situation, measured sets of QC samples (one for the Contractor and the other for the IVC) were prepared by the GJO Analytical Laboratory and are being introduced to the Contractor's and IVC's sampling protocol. This provides a cumulative cross comparison of the relative accuracy of the instruments and methods employed to assay smears.

Aside from the QC measures interjected by the IVC blind to the laboratory, the independent verification sampling benefits from the internal QC applied to the measurement process within the laboratory. Three measurement QCs are employed for each batch of smears. The laboratory inserts a preparation blank (PB), a laboratory control sample (LCS) and a continuing calibration

verification (CCV) for each batch of 21 smears. In this case, because each batch was larger than 21 smears, four sets of laboratory initiated QC measurements were made. Table 6-5 summarizes the internal QC measurements made for the smears from survey units 779-21 and 779-23.

Table 6-5. Results of the IV Laboratory Internal QC Measurements for Smear Samples

QC Sample Type	Expected Results	MDA	Measured Activity
	(Gross α , dpm)		
Preparation Blank	<MDA	5.33	0.49
Preparation Blank	<MDA	5.31	1.39
Preparation Blank	<MDA	5.33	-0.42
Preparation Blank	<MDA	5.33	-0.42
Laboratory Control Sample	475	7.53	432
Laboratory Control Sample	475	7.55	466
Laboratory Control Sample	475	7.53	454
Laboratory Control Sample	475	7.50	453
Continuing Calibration Verification	2220	16.83	2307
Continuing Calibration Verification	2220	16.81	2353
Continuing Calibration Verification	2220	16.74	2242
Continuing Calibration Verification	2220	16.96	2321

The analytical report presented results in pCi per sample. The results have been converted to dpm for presentation in this table. Since the smears were collected over a 100 cm² area, the results in dpm are equivalent to dpm/100 cm².

The internal QC data presented in Table 6-5 shows excellent agreement with the results expected.

6.2.2 Surface Media Samples

Stage II QC samples for the surface media sample sets are presented in Table 6-2. In addition to the Stage II QC samples, the IVC's laboratory performed internal QC measurements to assess the quality of the data produced. Three measurement QCs were employed for each of the three element groups (Am, Pu, U) processed for each survey unit. The laboratory inserted one PB, an LCS, and processed a duplicate of one randomly selected field sample for each sample batch. In all, there were seven PB, seven LCS, and two duplicate measurements made. Table 6-6 summarizes the PB QC measurements made. Table 6-7 summarizes the LCS measurements and Table 6-8 presents the duplicate sample measurements. Table 6-8 summarizes the cumulative paired duplicate measurement results collected from Survey Units 729-01, 779-04, 779-17, 779-21, and 779-23. A regression analysis was performed to assess the comparability between the first and duplicate measurements and is graphically presented in Figure 6-1.

The Internal QC data presented in Tables 6-5, 6-6, and 6-7 provide substantial indication that the data quality achieved in the surface media sample analysis is excellent.

Table 6-6. Results of the IV Laboratory Internal Blank QC Measurements for Surface Media Samples

Preparation Blank QC Sample (PB)	Expected Results	MDA	Measured Activity
	dpm/sample		
Am-241	<MDA	0.03	0.01
Am-241	<MDA	0.02	0.02 ^a
Am-241	<MDA	0.02	0.01

U-238	<MDA	0.05	-0.004

^aThe error in the reported result includes the MDA for the measurement.

Table 6-7. Results of the IV Laboratory Internal LCS QC Measurements for Surface Media Samples

Laboratory Control QC Sample (LCS)	Expected Results	MDA	Measured Activity
	pCi/mL (Am and Pu)		pCi/L (U)
Am-241	4.74	0.02	5.03
Am-241	4.74	0.02	4.87
Am-241	4.74	0.07	4.71
Pu-238	10.67	0.02	10.16
Pu-238	10.67	0.03	11.35
Pu-239/240	10.5	0.05	11.29
Pu-239/240	10.5	0.06	11.40
U-234	16.6	0.12	16.17
U-234	16.6	0.11	16.14
U-235	0.77	0.15	0.74
U-235	0.77	0.13	0.72
U-238	16.6	0.12	16.93
U-238	16.6	0.11	15.39

The units reported for the LCS measurements are different from those used in the rest of the analytical report. The selection of units of pCi/mL and pCi/L was based on convenience since the known value of the standard used is reported in pCi/mL and pCi/L. The function and utility of the LCS sample (comparing a measurement result with a known standard) are not compromised by using units other than those used to report sample results.

66

Table 6-8. Results of the IV Laboratory Internal Duplicate QC Measurements for Surface Media Samples

Duplicate QC Samples (D) Lab Sample ID#	Measured Activity (dpm/sample)			
	263398	263398D	263410	263410D
Am-241	2.02 ^a	1.49 ^a	6.28 ^a	7.28 ^a
Pu-238	0.14 ^a	0.02 ^a	0.50 ^a	1.56 ^a
Pu-239/240	1.28	2.01 ^a	27.58	49.05
U-234	67.91	70.77	32.44	31.40
U-235	2.38	5.44	1.45	1.92
U-238	70.53	75.03	33.88	31.39

^aEither the reported value is less than the MDA for the analysis or the error in the reported result includes the MDA. In this case, reproducibility between duplicate samples is not achievable with high confidence since relative error is high at sample concentrations near the MDA. That the duplicate samples yield results which are consistently at or near the MDA for the analysis provides evidence, in a qualitative sense, that duplicate measurements are comparable.

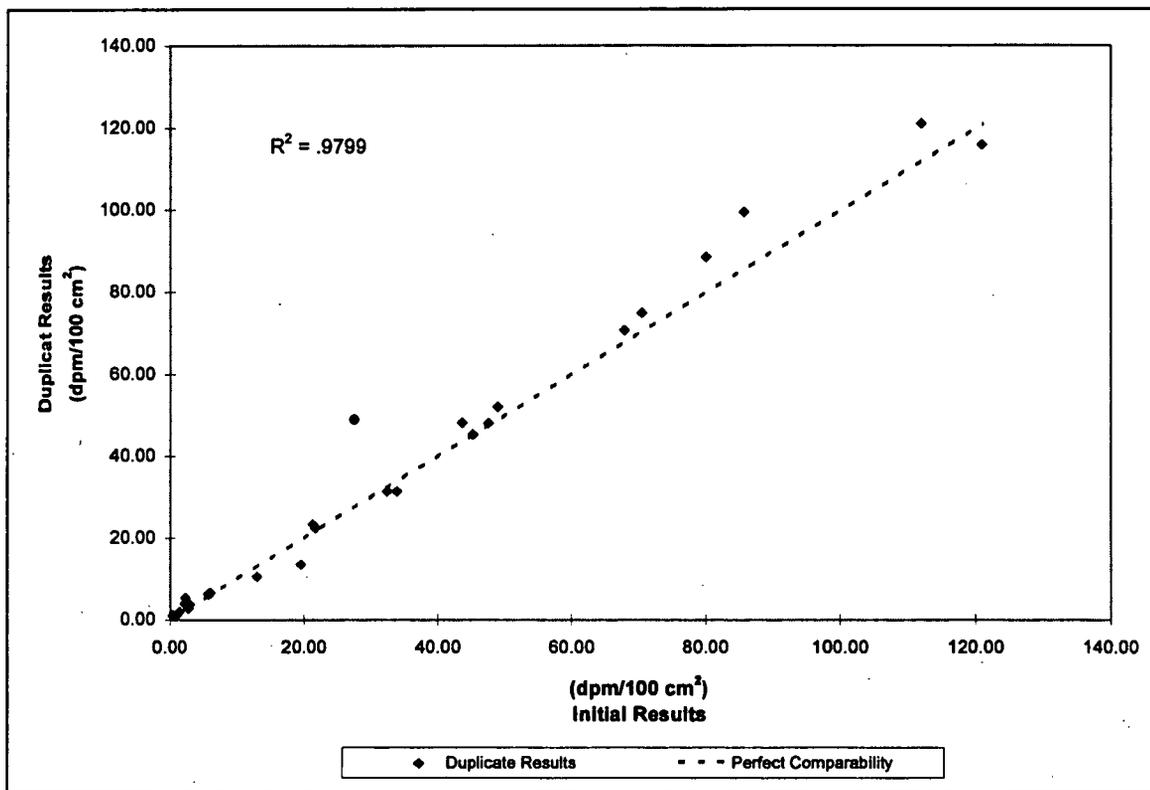

Figure 6-1. Comparison of Duplicate Alpha Isotopic Sample Analysis Results Linear Regression Fit Plot

6.2.3 Direct Static Measurements

Two sets of data collected by the IVC are pertinent to the assessment of direct static surface measurement data quality. They are replicate field measurement data and instrument response check data.

6.2.3.1 Replicate Field Measurements

The second of the two data sets contains the replicate measurements periodically made over the duration of the sampling period. Four replicate measurements were made in survey unit 779-21 and five were made in survey unit 779-23. Table 6-9 summarizes the cumulative paired replicate measurement results collected from survey units 729-01, 779-04, 779-17, 779-21, and 779-23. A regression analysis was performed to assess the comparability between the initial and replicate measurements and is graphically presented in Figure 6-2.

Table 6-9. Results of Replicate Direct Static Surface QC Measurements

Sample Location	Measured Activity(dpm/100 cm ²)

Linear Regression Fit Plot

6.2.3.2 Instrument Response Check Data

The first of the two data sets used to present the quality of direct static surface measurements is the response of the instruments (E600 with a HP-100 probe) to a planar source with a known amount of radioactivity. The source used was the same source used by the Contractor. It is an anodized surface source containing 2,398 dpm of Pu-239 radioactivity. The source was manufactured and certified to be NIST traceable by AEA Technology and assigned a unique ID# GM-785 (see copy of manufacturer's certification in Appendix B).

Prior to initiating a survey each day, periodically (≈every 2 hours), and at the end of a survey each day, the survey instrument in use was used to make a measurement on the known concentration source. The data sheets are provided for the two probes used by the IVC during the independent verification of survey units 779-21 and 779-23 (Appendix D). A total of 57 response check measurements were made with the probes during the survey period.

A control chart is provided for each probe (Figures 6-3, 6-4, and 6-5) to graphically portray the steadfastness of the instrument's responses to the source over the sampling period. Notable is the relatively tight band within which the response checks fall. No degradation of the instrument response was observed over the period it was used indicating that the 2 hour maximum use constraint on a fresh counting gas charge is adequate and might provide justification for a longer allowable period between purge and charge cycles.

7.0 Data Quality Analysis

The purpose of this data quality analysis (DQA) is to evaluate the data collected from the field in light of its intended use in decision making. Decision makers should obtain an understanding of the verity of the data used in the verification process from reading this section. The DQA uses guidance from *MARSSIM* (EPA 1997), *Guidance for Data Useability in Risk Assessment* (EPA 1992), information from the IV SAP (DOE 1999a), and professional judgement.

7.1 Detection Limit Adequacy

Each of the three measurement methods used to assess the residual radioactive contamination in Annex A have measurement sensitivities which limit the ability of the measurement to detect and quantify radioactivity. A key concern and design element of the SAP was to assure that sufficiently low detection sensitivities were achieved. Assumptions had to be made about the environment and response of the instrumentation and preparation methods in order to estimate the detection sensitivity before the fact. Now that the measurements have actually been made, assessment of the actual detection sensitivity achieved is possible. Section 6.0 presented data which demonstrated that the detection sensitivities achieved were adequate to identify and quantify radioactivity at a fraction of the applicable limit or DCGL. The target detection sensitivity planned for in the SAP was ≈ 50 percent of the applicable DCGL. Method detection limits obtained in both the field measurements and the laboratory measurements used were adequate to compare to the associated DCGL as indicated in Table 7-1, and met or exceeded the data quality target for measurement sensitivity.

Table 7-1. Adequacy of Independent Verification Measurement Detection Limits

Measurement	Analytical Method	DCGL Benchmark (dpm/100 cm ²)	Detection Sensitivity Achieved (dpm/100 cm ²)	
			779-21	779-23
Average removable surface contamination concentration	Smear counting	20	≈ 5	≈ 5
Average transuranic surface contamination concentration as measured by direct surface emission.	90 Second Direct Static Surface Emission Count	100	52 ^a	40 ^a
Maximum transuranic surface contamination concentration as measured by direct surface emission.		300		
Average surface transuranic contamination concentration in and beneath surface coatings as measured by surface media sampling.	Alpha Spectroscopy	100	≈ 2	≈ 2
Maximum surface transuranic contamination concentration in and beneath surface coatings as measured by surface media sampling.		300		
Average surface uranium contamination concentration in and beneath surface coatings as measured by surface media sampling.	Alpha Spectroscopy	5000	≈ 4	≈ 4
Maximum surface uranium contamination concentration in and beneath surface coatings as measured by surface media sampling.		15,000		
^a The detection sensitivity reported is net MDA. The adjusted gross MDA is equal to the MDA + background (76 dpm/100 cm ² and 52 dpm/100 cm ² respectively).				

If detection limits had exceeded the DCGL metrics, then declarations based on measurements made using that method could not have been substantiated. As evidenced by comparing the decision limits as represented by the DCGLs with the MDA associated with the measurement method employed in assessing the residual contamination in Annex A, each detection limit obtained was more than adequate to detect, observe, and make risk management decisions with confidence.

7.2 Sample Size and Statistical Power

According to the SAP, sample sizes were specified to ensure a false positive error rate (alpha error) and a false negative error rate (beta error) of no greater than 5 percent when measurement data sets were compared to the DCGL. For each sample media set—direct surface emission measurements, smears, and surface media samples—a sample size of 29 (allowing for a 20 percent contingency) was specified in the IV SAP (DOE 1999a). In the field, 58 direct surface emission measurements, 58 smears, and 18 surface media samples were actually collected from designated locations in Annex A. Only four sample locations in survey unit 779-23 met the criteria for sampling. The SAP does not adequately address a situation where the entire survey unit is stripped of all surface coatings and all direct static measurements are less than the critical detection level of 22 dpm/100 cm². The IVC determined that the Revised Sample Location Selection Protocol outlined in the SAP was not practical in this situation and made the decision not to take additional media samples.

Based on the results of each of the data sets, retrospective power curves were developed. Figures 7-1 through 7-4 illustrate the power of the sign test to conclude whether the null hypothesis should be rejected by measuring the probability that a survey unit meets the DCGL (except for surface media samples for survey unit 779-23). Values of both error types (Type I and Type II) can be derived from the power curve at any possible concentration of residual contaminant. Type-I errors (falsely concluding that the DCGL is not exceeded when it actually is exceeded) are those that concern the risk manager and decision maker most. The actual and critical sample size (N) are both presented for each of the four data sets evaluated. The retrospective power curve is calculated using the actual sample size obtained. The boundary of the gray region represents the concentrations between which there is insufficient power at the prescribed alpha and beta error rate, given the sample size obtained and the variability observed in the data set. Process knowledge of the technique used by the Contractor to remove contamination from the surface area of the concrete and direct static surface measurements (all well below the DCGLs) are used to demonstrate the small probability of remaining contamination exceeding the DCGLs.

Inspection of Figure 7-1 illustrates that the Type-I error rate drops below 5 percent (the error rate is 1-Power) when the true mean surface contamination concentration is at the DCGL of 100 dpm/100 cm², the sample size is 29, and the standard deviation is 14.45 dpm/100 cm² (the actual standard deviation). Alternately, the power to reject the null hypothesis when the mean surface contamination concentration is as high as 85 dpm/100 cm² is 95 percent. The critical sample size required to provide the power necessary to meet the sampling objectives outlined in the SAP was determined to be 19. The actual sample size (29) was much higher than that required, thus the actual power was much higher than required by the sample design. Note that the estimate of the central tendency, the geometric mean, is plotted against the power curve. This concentration is significantly less than the concentration at which the power begins to wane (the

94

lower boundary of the gray region). The power to reject the null hypothesis at the observed mean concentration in the survey unit is effectively 100 percent.

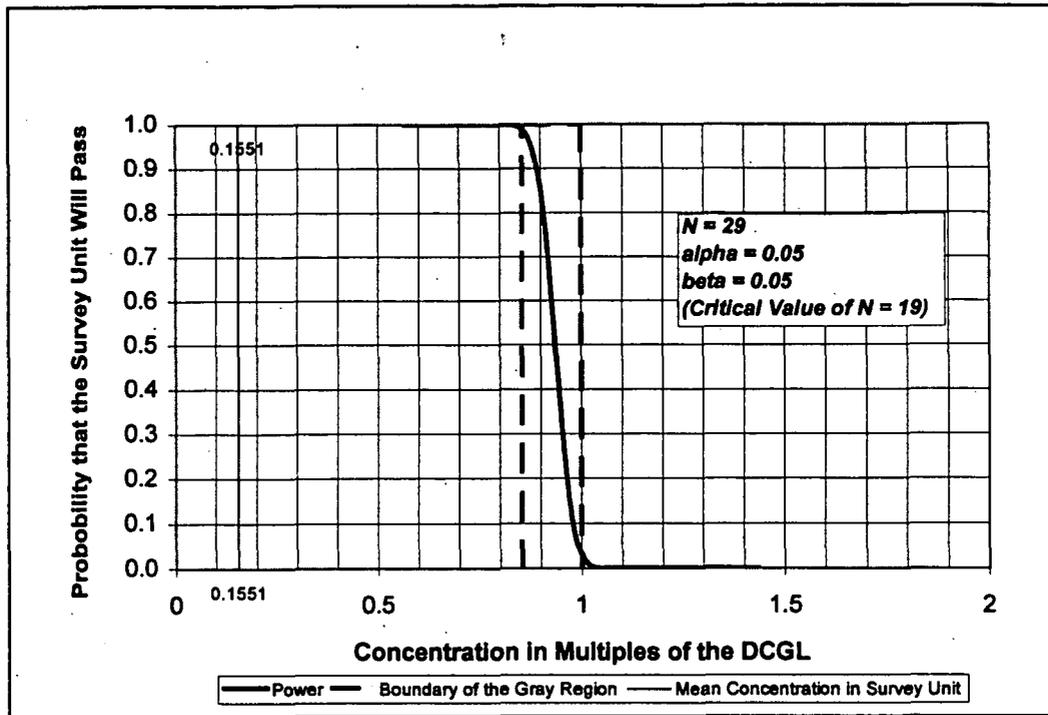

Figure 7-1. Retrospective Power of the Sign Test
Direct Static Surface Measurements, 779-21

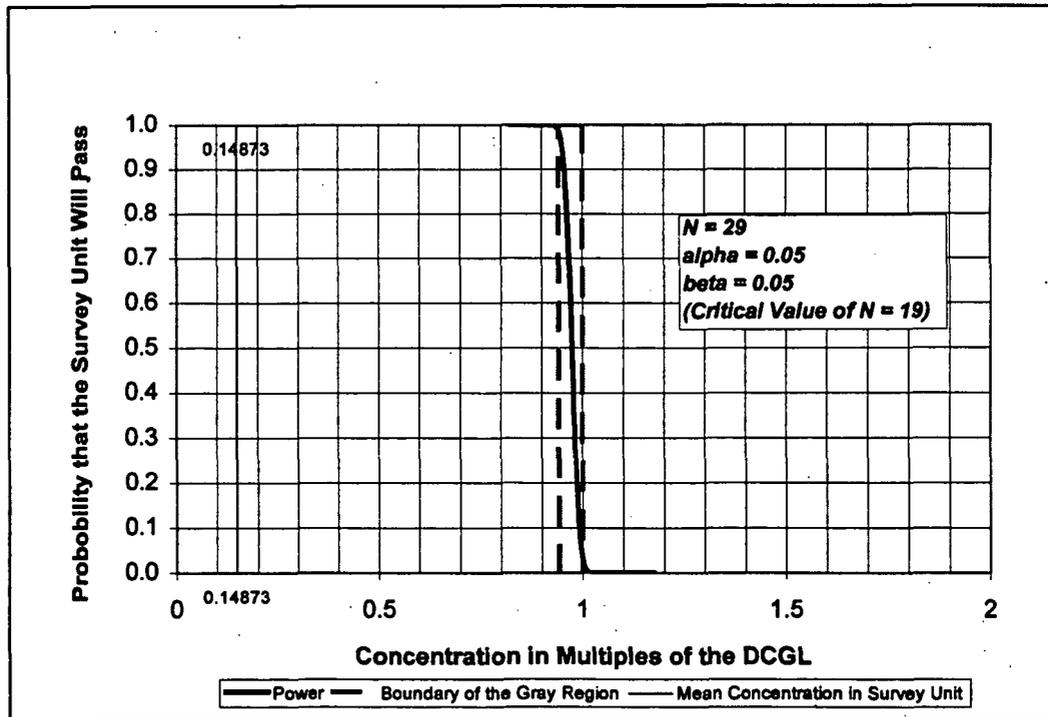

Figure 7-1 (continued). Retrospective Power of the Sign Test
Direct Static Surface Measurements, 779-23

95

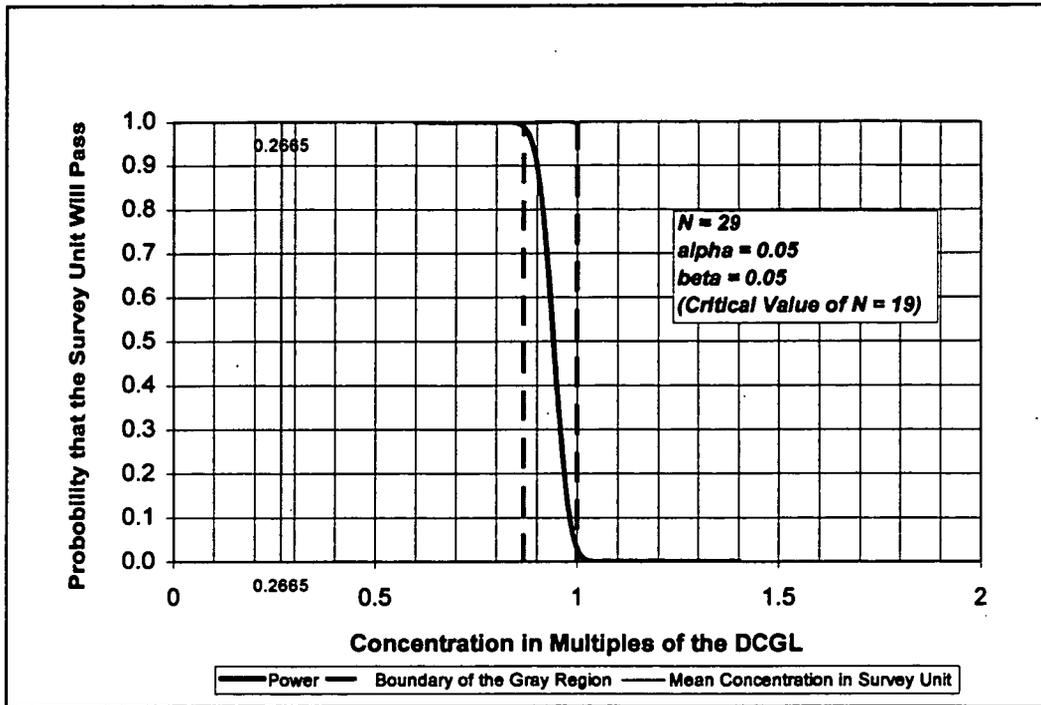

Figure 7-2. Retrospective Power of the Sign Test Smear Sample Measurements, 779-21 and 779-23

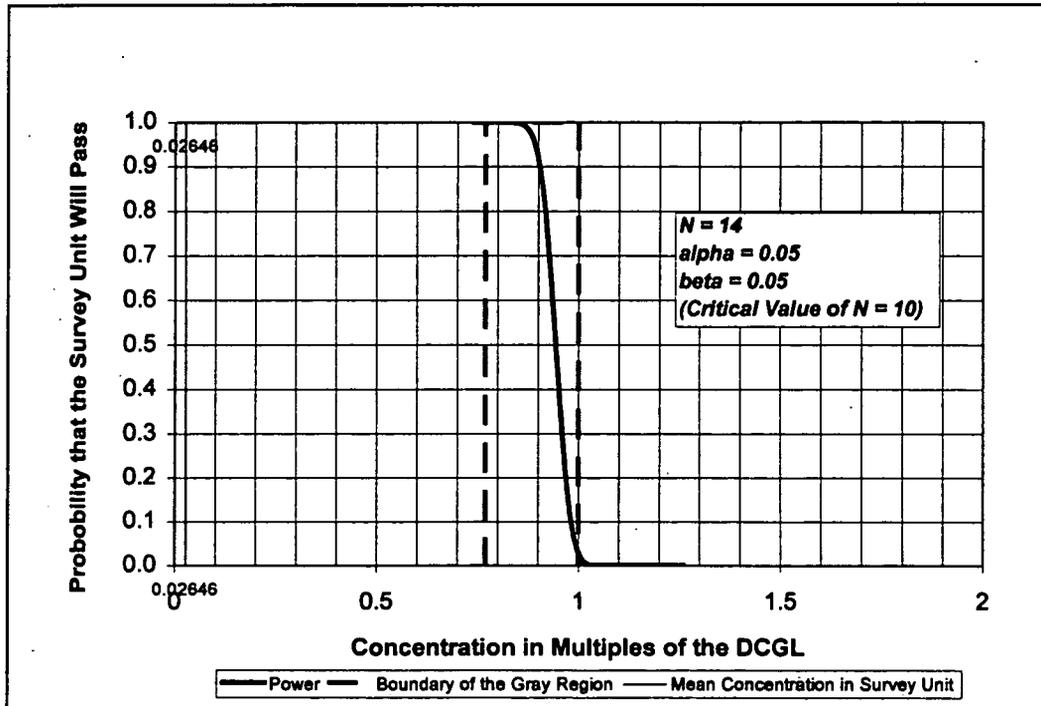

Figure 7-3. Retrospective Power of the Sign Test Surface Media Samples/Transuranic Activity, 779-21

96

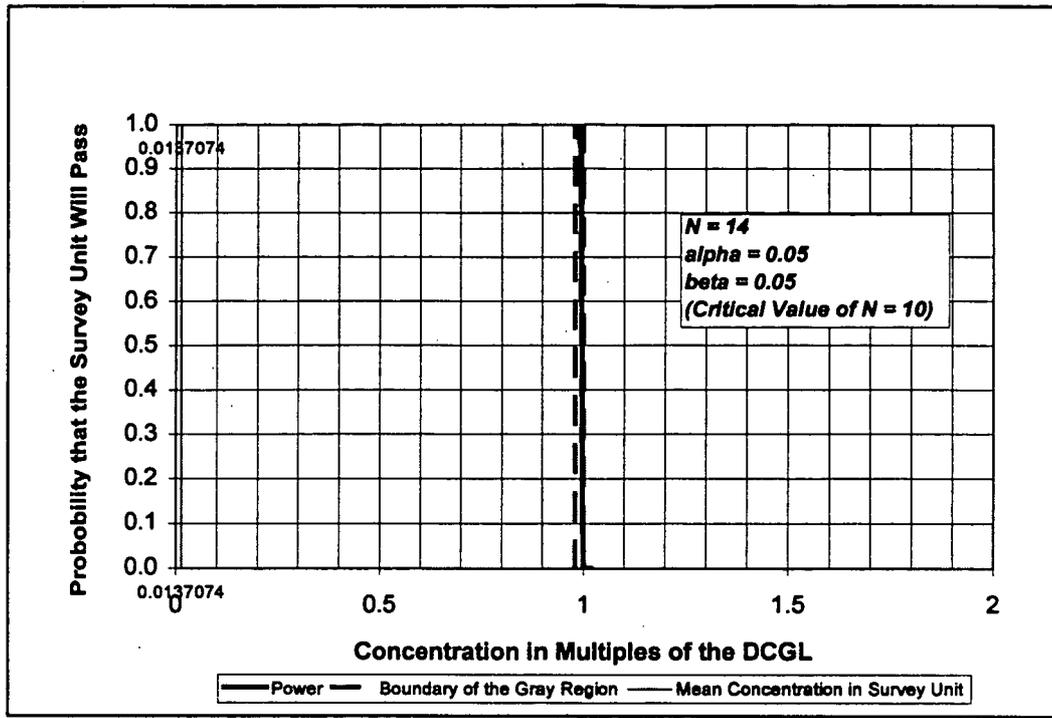

Figure 7-4. Retrospective Power of the Sign Test
Surface Media Samples/Uranium Series Activity, 779-21

The same results are observed in Figures 7-2 through 7-4. Rigorous statistical tests of the data sets are not justified since it is known that every data point comprising each of the data sets was less than the applicable DCGL. When this occurs, the sign test will always conclude that the null hypothesis should be rejected, provided that a sufficient number of measurements have been included in the data set (i.e., actual sample size is greater than or equal to the critical sample size). Thus, risk managers can be assured that the data collected is sufficiently robust to decide that the residual surface contamination concentration in the survey units measured is below the DCGL.

7.3 Measurement Uncertainty and Data Quality Indicators

As discussed in the IV SAP (DOE 1999a), measurement uncertainty stems from two sources: field sampling variation, and instrument/laboratory measurement variation. Of the two sources, field sampling variation was noted as the greatest contributor to overall uncertainty because of the inherent logistics of sample collection and the one-of-a-kind aspect of sampling the building. The field measurement methods used in the building survey were standard Health Physics instrument techniques and were governed by approved procedures used in the field sampling process. Laboratory procedures were also utilized by the GJO Analytical Laboratory to assess the radioactivity associated with both smear samples and surface media samples. Surface media samples were weighed prior to sample preparation to minimize error due to sample mass loss during sample preparation. An additional control feature utilized to minimize variability and error in the surface media samples was to homogenize the sample by grinding the surface veneer material removed to a fine powder. In this way, any aliquot of the sample selected for analysis could be confidently expected to yield comparable results.

As discussed in the SAP (DOE 1999a), an important activity in determining the usability of the data based on sampling is assessing the effectiveness of the sampling program (EPA 1998, EPA 1992). Data Quality Indicators (DQIs) were identified as guidelines for the DQA process to provide quantitative and qualitative measures of overall data quality and usability. For comparative purposes, Table 7-2 repeats the target DQIs from the IV SAP and summarizes the post-sampling data quality assessment.

Inspection of Table 7-2 indicates that the DQIs are achieved and the data is regarded as having sufficient quality to be useable for verification of the DCGL and for assessing the results and conclusions obtained by the Contractor.

7.4 Overall Quality Assurance and Quality Control

Based on the forgoing analysis and observed practices in the field, it is apparent that overall project QA/QC goals were obtained. The key technical features of the project included:

The DCGL derivation and SAP development processes were performed in accordance with EPA guidance for DQOs (EPA 1997 and EPA 1993).

Field operations were conducted in accordance with the SAP. Modifications to the sample locations which were either inaccessible or involved appreciable personnel safety hazards were made in accordance with the approved sample relocation procedure outlined in the SAP.

Data analysis was conducted as prescribed by the SAP and in general agreement with EPA guidance (EPA 1997 and EPA 1992).

There were no significant problems or incidents that would compromise the findings. The data collected from the building survey is regarded as useable.

916

Table 7-2. Target Data Quality Indicators and Findings

DQI	Quality Objective (DOE 1999)	Significance	Action/Remark	Finding
Completeness	90 percent completeness	Less than complete data set could decrease confidence in supporting information.	Fifty-eight direct surface emission measurements of the 58 scheduled for the survey units were obtained (100 percent).	DQI accepted.
			Fifty-eight smear samples of the 58 scheduled for the survey units were collected (100 percent).	DQI accepted.
			Fourteen of the potential 29 surface media samples were collected (48 percent) in survey unit 779-21 and four were collected in survey unit 779-23 (14 percent). No other sample location met the inclusion criteria for sampling. More than 95% of the survey units were hydrolysed and stripped of surface coatings. It was determined impractical to find alternate locations and additional samples were not collected. An assessment of the <i>a posteriori</i> power provided by the surface media sample data set provides evidence that the sample size of 14 for survey unit 779-21 is sufficient to be considered complete. Although the sample size of four for survey unit 779-23 is determined to be insufficient, the data set for direct static measurements provides sufficient evidence that residual contamination in and beneath the surface is less than the DCGL.	DQI accepted.
Comparability	1) Comparability between instrument efficiencies (~ ±10 percent) 2) Common or equivalent sampling procedure used. 3) Professional judgement and field observations.	Affects ability to combine data sets produced using different sampling and/or analytical methods.	No measurement data sets were combined for the independent verification of the Final Status Survey of Annex A. Consistent methods, both sampling and analytical, were used throughout the sampling and survey process.	DQI accepted.
Representativeness	Sample allocation approach followed to ensure unbiased sample location selection and spatial distribution of the sampling locations.	Non-representativeness increases or decreases Type I error depending on the bias and results in the need to collect additional samples to improve representativeness.	Sample allocation used in the field strictly followed the approach outlined in the SAP. Three of the 58 sample locations selected at random had to be relocated for personnel safety or location accessibility reasons. Each of these were relocated using the relocation protocol outlined and approved in the SAP and maintained the spatial and unbiased objectives of the sample allocation objective. Each of the 58 sample locations was selected without prior knowledge and is unbiased. The sample locations selected meet the intent of the SAP design and are considered representative of conditions in the building. There are no analytical or measurement effects (e.g., holding times or compositing effects) affecting representativeness.	DQI accepted.

Table 7-2 (continued). Target Data Quality Indicators and Findings

DQI	Quality Objective (DOE 1999)	Significance	Action/Remark	Finding
Precision	<p>Field and laboratory processes will be governed by procedures.</p> <p>Replicate and split samples are used to assess variability as an indicator of precision.</p> <p>< 10% difference between replicate and split samples.</p> <p>Overall r^2 of ≈ 0.75 or better on paired data sets.</p> <p>Standard error of the regression estimate (SSE $\pm 10\%$).</p>	Lack of precision affects the accuracy or confidence in the accuracy of the reported results.	<p>All sampling, field measurement, and laboratory analysis processes were controlled by approved written procedures. Replicate direct static surface measurements made in the field showed poor precision at the low count rates encountered at most sample locations (most were below the detection limit for the method).</p> <p>Regression analysis on the paired data yielded a regression coefficient of determination of 0.39 and a standard error estimate of 6.15%. The target r^2 of ≈ 0.75 indicated in the SAP was established with the assumption that residual contamination would be greater than background and will be changed to reflect actual field conditions at or near background.</p> <p>Field instrument response checks and laboratory control standards and continuing calibration verification measurements demonstrated the precision of the laboratory analytical methods showing less than 10% error when control samples were measured more than once.</p> <p>Caution must be exercised when attempting to measure precision on replicate measurements with activity near and below the detection limit. Statistical variability at near zero activity limits the likelihood that measurements results will be precise even when sampling and analytical methods are in fact precise and suitable at concentrations approaching the DCGL.</p> <p>Overall sampling variability is another measure of precision. Quantitative metrics describing measurement precision are all acceptable. CV's range from 0.42 to 0.97 and the CI_{95} for each data set was more than 50% below the applicable DCGL.</p>	DQI accepted.
Accuracy	<p>Field and laboratory processes will be governed by procedures.</p> <p>Response to samples containing known amounts of radioactivity should be within $\pm 10\%$.</p> <p>QC Blank samples should return results below detection limit. QC spike samples should return results indicating the presence of the radioactivity of interest.</p>	Accuracy is affected by bias and precision. A lack of accuracy can affect Type I and Type II errors depending on the bias.	All procedures were implemented. Spikes and Blanks returned expected results. Responses to samples (or sources) containing known amounts of radioactivity were consistently within $\pm 10\%$ for every analytical measurement method used. Field responses to a low-level source containing a known amount of radioactivity were consistently within the acceptable range of $\pm 20\%$. As shown above, precision was acceptable	DQI accepted.

CV = Coefficient of Variation CI = Confidence Interval r^2 = Coefficient of determination

100

8.0 Summary and Conclusions

8.1 Independent Verification Sampling and Survey

On the basis of the analysis presented in Sections 3.0 through 7.0 of this report, the IVC has demonstrated that the Annex A survey units selected for independent verification (779-21 and 779-23) have met each of the compliance benchmarks, or DCGLs. These results show that residual surface radiological contamination is well below the agreed upon benchmarks for the Building 779 Cluster Decontamination and Decommissioning Project applicable to Annex A. Table 8-1 provides a summary review of the DCGLs compared to the appropriate compliance parameter. The independent verification sampling and survey results are highly reliable and consistent with the field sampling and survey design. No unexpected results or trends are evident in the data. The sampling and survey results determined that residual radiological contamination in Annex A is very minimal and, for the most part, barely above background levels. Thus, the IVC concludes that the null hypothesis for survey units 779-21 and 779-23 (that residual radiological surface contamination exists in concentrations above the DCGLs) should be rejected.

Table 8-1. Comparison of Annex A DCGLs to Observed Compliance Parameters

Metric	Surface Radioactivity (dpm/100 cm ²)				Pass/Fail	
	DCGL	Actual		779-21		779-23
		(UCL ₉₅)				
		779-21	779-23			
Mean surface contamination as measured by direct surface emission	100	25.8	17.1		Pass	
Maximum surface contamination as measured by direct surface emission	300			78.6	24.7	Pass
Mean removable surface contamination	20	<5.33	<5.33			Pass
Mean total transuranic surface contamination on and beneath a surface with a surface coating as measured by surface media sample	100	7.2	2.3			Pass
Maximum total transuranic surface contamination on and beneath a surface with a surface coating as measured by surface media sample	300			34.4	1.7	Pass
Mean total uranium series surface contamination on and beneath a surface with a surface coating as measured by surface media sample	5000	86.5	66.4			Pass
Maximum total uranium series surface contamination on and beneath a surface with a surface coating as measured by surface media sample	15,000			141	48.5	Pass

8.2 Independent Review of the Contractor's Final Status Survey Report and Conclusions

The IVC has completed a comprehensive review of the Contractor's Closeout Radiological Survey Report for Building 779, Annex A (RMRS 1999c) and concurs with the conclusion reached by the Contractor—that each survey unit in Annex A met the applicable DCGLs and that the building should be released from further radiological controls.

ANALYTICAL SUMMARY

This report contains the results for sixty-six smear samples received on October 29, 1999, under Project No. 342303001 and Requisition No. 16821.

On page 14 of Section II, the analyst notes that the envelope for sample SMR0000591 (lab ID 263362) was received empty and the envelope for sample SMR0000592 (lab ID 263363) contained two smears. Since the samples appeared to be control blanks, the analyst chose to count one as sample 263362 and the other as sample 263263. The results for both samples were below detectable levels. After counting, the smears were returned to the envelope in which they were received.

The determination of gross alpha activity was done by gas proportional counting according to the Grand Junction Office Analytical Laboratory Standard Operating Procedure (SOP) RC-8. Duplicate analysis results were obtained by counting the same sample twice.

All applicable laboratory quality control parameters were met.

RADIOCHEMICAL
SUPPORTING DOCUMENTATION

Requisition No. 16821

The following section contains the analytical supporting documentation for the radiochemical analyses performed on this request. Commonly used laboratory codes in this section include:

PROCEDURE:

RC-8: Gross Alpha/Beta Analysis

QUALITY CONTROL PREFIXES

PB:	Blank
LCS:	Laboratory Control Sample
CCV:	Continuing Calibration Verification

This section contains 41 pages numbered 1 through 41.

Determination of Gross Alpha & Gross Beta

Worklist ID: 99116163

Hustan R. Ba

11-04-99

Chemist ID: G40349

Sample prep. procedure: RC8 R03
 Analysis procedure: RC-8 R03
 Date of sample prep.: 11/03/99

Instrument Conditions
 Instrument: CAN2404
 High Voltage: 1525

Calibration Data

	Alpha	Beta
Efficiency:	0.1839	0.2528
RSD (%):	2.06	1.50
N:	6	6
**Uncertainty (%):	2.00	1.49
Background CPM:	0.077	0.81
Count time of background (min):	60.0	60.0
Half-life for decay correction (y):	432.7	28.6
Crosstalk (%):	0.17	19.06

** Uncertainty of the calibration standard activity.

Uncertainty is calculated with 1.96 sigma.
 MDA is Minimal Detectable Activity.

Calculations by: GABAF v1

CCV is #108 calibration
 CCV recovery
 $= \frac{1039}{1000} = 103.9\%$
 CCV recovery
 $= \frac{2049}{2010} = 101.9\%$

Instrument Conditions
Instrument: CAN2404
High Voltage: 1525

Calibration Data	
Alpha	Beta
Efficiency: 0.1839	0.2528
RSD (%): 2.06	1.50
N: 6	6
**Uncertainty (%): 2.00	1.49
Background CPM: 0.077	0.81
Count time of background (min): 60.0	60.0
Half-life for decay correction(y): 432.7	28.6
Crosstalk (%): 0.17	19.06

** Uncertainty of the calibration standard activity.

Uncertainty is calculated with 1.96 sigma.
MDA is Minimal Detectable Activity.

CCV is #1 of calibration.

CCV recovery

$$= \frac{1060}{1000} = 106.0\%$$
 CCV recovery

$$= \frac{2043}{2010} = 101.6\%$$

Additional Comments:

Sample Prep Procedure: RC8 R03

Analysis Procedure: RC-8 R03

Date of sample prep: 11-04-1999

** LCS = 5.0 mL of LCSWR24, known values: alpha 214, beta 230.

Actual Conditions:

Req. No.: 16821

Worklist ID: 99116164

Analysis: SWIPE

The paper envelope for sample 263362 was received EMPTY and the envelope for sample 263363 was received containing two smears. It appeared that both of these smears were control blanks, so I chose one to count as sample 263362 (labeling the glassine envelope as #1) and one to count as sample 263363 (labeling the glassine envelope as #2). The samples were counted and the results for both were below detectable levels. After counting, both smears were returned to the paper envelope in which they were received.

GRB 11/4/99

Calibration Data

	Alpha	Beta
Efficiency:	0.1839	0.2528
RSD (%):	2.06	1.50
N:	6	6
**Uncertainty (%):	2.00	1.49
Background CPM:	0.077	0.81
Count time of background (min):	60.0	60.0
Half-life for decay correction (y):	432.7	28.6
Crosstalk (%):	0.17	19.06

** Uncertainty of the calibration standard activity.

Uncertainty is calculated with 1.96 sigma.
 MDA is Minimal Detectable Activity.

CCV is #1 of calibration
 CCV recovery
 $= \frac{1010}{1000} = 101.0\%$

CCV β recovery
 $= \frac{2029}{2010} = 100.9\%$

Calculations by: GABAF v1

Sample prep. procedure: RC8 R03
 Analysis procedure: RC-8 R03
 Date of sample prep.: 11/04/99

Instrument Conditions
 Instrument: CAN2404
 High Voltage: 1525

Calibration Data	
Alpha	Beta
Efficiency: 0.1839	0.2528
RSD (%): 2.06	1.50
N: 6	6
**Uncertainty (%): 2.00	1.49
Background CPM: 0.077	0.81
Count time of background (min): 60.0	60.0
Half-life for decay correction(y): 432.7	28.6
Crosstalk (%): 0.17	19.06

** Uncertainty of the calibration standard activity.

Uncertainty is calculated with 1.96 sigma.
 MDA is Minimal Detectable Activity.

CCV is #1 of calibration
CCV & recovery

$$= \frac{1046}{1000} = 104.6\%$$

$$\text{CCV } \beta \text{ recovery} = \frac{2097}{2010} = 104.3\%$$

ANALYTICAL REPORT INDEX

This report is the final data package for Requisition 16822 generated by the Analytical Laboratory for the Rocky Flats IVP project. It is the official record, and requestors are responsible for proper record-keeping in compliance with project requirements.

This report was prepared as an account of work sponsored by an agency of the United States Government. Neither the United States Government nor any agency thereof, nor any of their employees, makes any warranty, express or implied, or assumes any legal liability or responsibility for the accuracy, completeness, or usefulness of any information, apparatus, project, or process disclosed in this report, or represents that its use would not infringe privately owned rights. Reference therein to any specific commercial product, process, or service by trade name, trademark, manufacturer, or otherwise, does not necessarily constitute or imply its endorsement, recommendation, or favoring by the United States Government or any agency thereof. The views and opinions of authors expressed herein do not necessarily state or reflect those of the United States Government or any agency thereof.

ANALYTICAL SUMMARY

This report contains the results for twenty-four samples of various solids logged in on October 29, 1999, under Project Number 342303001 and Requisition Number 16822.

The samples were submitted for the determination of americium-241, plutonium isotopes, and uranium isotopes.

The samples were analyzed by alpha spectrometry according to the Grand Junction Office Analytical Laboratory Standard Operating Procedure (SOP) RC-19.

All laboratory quality control parameters were met during the course of these analyses.

RELEASE OF THE DATA CONTAINED IN THIS REPORT HAS BEEN AUTHORIZED BY THE LABORATORY MANAGER OR THE MANAGER'S DESIGNEE

RADIOCHEMICAL SUPPORTING DOCUMENTATION

Requisition Number 16822

The following section contains the analytical supporting documentation for the determination of americium-241, plutonium isotopes, and uranium isotopes. Commonly used laboratory codes in this section include:

PROCEDURES:

RC-19: Alpha Spectrometry

QUALITY CONTROL ABBREVIATIONS:

LCS: Laboratory Control Sample
PB: Preparation Blank

This section contains 193 pages numbered 1 through 193.

Comments and Actual conditions:

- Start date: 11/1/99
- Automatic pipets calibrated in accord with QC-6 on balance # 9
- Balance # 8 used for weights of samples and their aliquots
- Sample aliquot is the fraction of the total sample taken for analysis

Comments and Actual conditions:

- Start of digestion: 11/11/99
- Automatic pipets calibrated in accord with QC-6 on balance # 18
- Samples weighed on balance # 8
- *After sample dissolution, a Barium Sulfate preconcentration was done followed by a carbonate conversion (Both done as stated in RC-19 R06)
- Sample aliquot is the fraction of the total sample taken for analysis

Comments and Actual conditions:

- Start date: 11/1/99
- Automatic pipets calibrated in accord with QC-6 on balance # 9
- Balance # 8 used for weights of samples and their aliquots
- Sample aliquot is the fraction of the total sample taken for analysis

OK on 11/10/99
Richard S. Brant

Comments and Actual conditions:

- Start date: 11/1/99
- Automatic pipets calibrated in accord with QC-6 on balance # 9
- Balance # 8 used for weights of samples and their aliquots
- Sample aliquot is the fraction of the total sample taken for analysis

Comments and Actual conditions:

- Start date: 11/1/99
- Automatic pipets calibrated in accord with QC-6 on balance # 9
- Balance # 8 used for weights of samples and their aliquots
- Sample aliquot is the fraction of the total sample taken for analysis

Final Report to J. Lively

Requisition No. 16822

Office/Tech. Bldg 3022, 206A

Project No. 342303001

Project Rocky Flats IVP

Date Submitted 10/28/99

Area Building 779 Cluster

Site ID No. Survey Unit 779-21

Number of Samples 20¹⁹⁹ 24

Results Required

- * Immediate: 1 to 16 hours
- * Expedite: up to 48 hours
- Normal schedule: 4 to 14 days
- Delay acceptable: more than 14 days

* Justification _____

Analysis Required

- Airborne Silica
- Airborne Asbestos
- Airborne Radioparticulate
- Bulk

- Asbestos
- Soil
- Metals
- Water
- Other concrete, cinder block

Elemental (Use Symbol)

- As
- Ba
- Cd
- Cr
- Pb
- Hg
- Se
- Ag

Isotope (Use Symbol)

- Ra-226
- Th-230
- U-Nat
- Po-210
- Pu-238
- U-234
- 239
- 240/241
- Am-241
- 235
- 238

Other Analysis

- Volatiles
- Semi-volatiles
- PCBs
- pH
- Ignitability

Special Instructions Retain samples until determined by

Jeff Lively

CRDL = 2.5 pCi / sample per nuclide

Please report results in dpm / sample

RELEASE EVALUATION FORM

Page 1 of 2

Release Evaluation No.: 991027-00779-001 EXTENDED: No EXPIRES.: n/a Charge No.: n/a

PART I SENDER/CUSTODIAN ACKNOWLEDGEMENT

Description of Property/Waste/Sample To Be Released/Transferred:

24 surface media samples and 66 smears from rooms 143/144/145/146/147/148/151/152

Current Location: B7779 Cluster

Destination: GJO Analytical Chemistry Laboratory, Grand Junction CO.

New Recipient/Custodian: Ron Chessmore 970-248-6166

History/Process Knowledge: Surface media samples and smears obtained for independent verification after final survey.

Has the specified material ever been in an RMM/RBA/CA or contacted DOE controlled radioactive materials? Yes, Annex A was part of a CA.

- 1) By signing below, I certify information provided in Part I of this release evaluation to be true and accurate.
- 2) By signing below, I agree to comply with the specific requirements noted in Part II of this release evaluation.

Art Samiljan

Sender/Custodian: Art Samiljan Employee No. [REDACTED] Date: 10/27/99 Ext 2863 Pager N/A

PART II RADIOLOGICAL ENGINEERING

SPECIFIC REQUIREMENTS AND/OR COMMENTS:

Based on the fact that all final survey surface media samples obtained in rooms 143, 144, 145, 146, 147, 148, 151, and 152 met the unrestricted release criteria, these additional independent verification surface media samples may be released for unrestricted use with no rad screening required. In addition, all measurements obtained to date for final survey indicate no alpha contamination above the unrestricted release limits of 100 dpm/100 cm² total or 100 dpm/100 cm² removable exists in the above referenced rooms. Therefore the independent verification smears obtained may be free released as well.

PROPERTY/WASTE RELEASE EVALUATION SIGNATURE REQUIREMENTS

Release Evaluation #: 991027-00779-001 Page 2 of 2

Release Evaluation for Waste:

A Release Evaluation for Waste requires an evaluation and unrestricted release approval signature. The evaluation signature is by the Radiological Engineer (RE) providing the methods or criteria for unrestricted release (i.e., survey requirements, analytical requirements, no survey required, etc.). The unrestricted release approval signature for a Release Evaluation for Waste shall be a RE authorized to provide unrestricted release approval. In addition, the evaluation and unrestricted release approval signatures shall not be the same RE. The intent of this provision is to provide peer review of the evaluation and method of unrestricted release. It is important the RE take the peer review process seriously and not become a "rubber stamp" for their fellow engineer.

Release Evaluation for Property:

A Release Evaluation for Property requires an evaluation and unrestricted release approval signature. For a Release Evaluation for Property, the evaluation and unrestricted release signature may be the same RE. In the past, only one signature was required for property for which a RE could provide an unrestricted release on the basis of process knowledge/history.

Release Evaluation for Samples:

Samples are any waste or material that is being shipped to an off-site facility for analysis. Samples that may be provided with an unrestricted release using process knowledge/history or standard contamination survey techniques may be authorized for shipment to an off-site facility using the signatory requirements specified for property. Samples which cannot be provided with an unrestricted release using process knowledge/history or standard contamination survey techniques shall be authorized for shipment from the Site using the methodology specified for waste, i.e., second signature being provided by a RE authorized to perform peer review and approval for shipment.

The approval for transfer/shipment section of a Sample Release Evaluation (SRE) shall be revised as noted below for samples which cannot be provide with an unrestricted release.

"The samples specified in Part 1 of this release evaluation are being provided with authorization for transport as non-radioactive materials in accordance with Department of Transportation (49 CFR) regulation. This authorization for shipment does not constitute an unrestricted release."

Additional Documentation:

Number of lines per section may be modified or additional pages attached to ensure adequate documentation of information necessary to perform release evaluation.

Additional pages or attachments to a release evaluation shall have the evaluation number, Page ___ of ___, initials of Radiological Engineer signing approval for transfer/shipment and date.

Service Request No. N/A PASSED FAILED

(Reason) PROBE CALIBRATION FOR USE @ RFETS, IVC SURVEYS

6. ^{LIMITED} Calibration Sticker and Interval

New Sticker Attached Due Date 6/30/2000

This calibration complies the requirements of ANSI 323-1978 and 10 CFR 835, and has been calibrated using standards whose accuracy is traceable to the National Institute of Standards and Technology.

Signature JW Lively Date 6/30/99

#1 THIS IS PERFORMED as part of the field Q.C. of the HP-100 probe when response checks are performed for the probes every hour during field use. Experience shows that probe efficiency (α) does not degrade more than 20% over the 2 hour period a probe is used. See attached graphs.

#2 Plateau Graph was not printed out for the record since no printer was available in the field. The selected high voltage (1592 vdc) result in <1% β → α crossover.

Appendix H

Raw Data

This appendix contains the raw ASCII text file data download directly from the E-600 instrument's memories without modification, sorting, or data reduction of any kind. The data are actually contained in three separate ASCII files; one file corresponding to each date in which information was collected. One unique aspect of this data presentation is that the data is presented exactly in the chronological order in which it was collected in the field. This provides an electronic time stamp permitting verification that time criteria included in the field operating procedures associated with the IV SAP were met.
