Piqua, Ohio, Decommissioned Reactor Site

This fact sheet provides information about the Piqua, Ohio, Decommissioned Reactor. This site is managed by the U.S. Department of Energy Office of Legacy Management under the DOE Defense Decontamination and Decommissioning (D&D) Program.

Site Description and History

The Piqua, Ohio, Decommissioned Reactor Site is located in southwestern Ohio in the city of Piqua on the east bank of the Great Miami River, about 30 miles north of Dayton. The site is approximately 900 feet southeast of the Piqua municipal power station and 150 feet north of the city sewage treatment plant. A limestone quarry frames the north and east sides of the reactor site. The decommissioned reactor is about 120 feet from the Great Miami River.

The first 45.5 megawatt, organically cooled and moderated, thermal reactor was built by the U.S. Atomic Energy Commission (AEC) — predecessor agency to the U.S. Department of Energy (DOE) — as a demonstration project. The prototype used a commercially available mixture of aromatic hydrocarbons called terphenyls to cool the reactor. The 27-foot-tall vessel was made of low-carbon steel and its 7.6-foot-diameter interior had an average wall thickness of 2 inches. The reactor produced 150,000 pounds per hour of 550°F superheated steam, at a pressure of 450 pounds per square inch. The steam was pumped through footbridge pipes across the Great Miami River to turbo generators in the Piqua municipal power plant to augment the city’s power supply.

Beginning in June 1963, AEC contracted the city of Piqua to operate and maintain the facility. The reactor was shut down in January 1966 because of economic and technical considerations. AEC terminated its contract with the city of Piqua in 1967 and dismantling and decommissioning activities began that year. Decommissioning was completed in 1969 and the reactor vessel was entombed on-site.

Construction of water retarding dams and basins in 1921 greatly reduced river flooding throughout the Great Miami River Basin. One of the dams, constructed 4 miles upstream of Piqua, was designed to work with levees and river channel improvements to permit a maximum river flow of 80,000 cubic feet per second at the site. Since the dams were constructed, the highest river flow at Piqua was 22,000 cubic feet per second in 1929 and 1933. The river elevation during that flow was about 9 feet below the main floor level of the reactor building. The flow data was collected at the U.S. Geological Survey station 03262500 in Piqua. Between 2013 and 2016, flow in the Great Miami River at Piqua ranged between 753.8 to 1,152 cubic feet per second.
Facility Decommissioning

Between 1967 and 1969, AEC removed the reactor fuel, coolant, and most of the radioactive materials from the site. Contaminated piping and equipment inside the reactor building were removed or decontaminated. The reactor vessel, concrete biological shield (bioshield), and nonremovable parts of the vessel were left in place. Contamination remaining in the reactor is mainly from activation products — materials that were once stable but became radioactive due to operations — in the reactor core.

Facility structures currently consist of the reactor building and a connected auxiliary building. The belowground portion of the reactor building is an upright steel, cylindrical structure that contains the reactor vessel, steam-generating equipment, and other parts of the heat transfer system. The city of Piqua used the facilities for offices, meeting rooms, and storage.

The reactor vessel is entirely belowground and surrounded by an 8-foot-thick concrete bioshield. Approximately 2 feet of the interior of the bioshield is contaminated with activation products. However, the fuel (enriched uranium) has been removed from the core area of the reactor, and since the facility was designed to contain radioactivity from
an operating reactor, the bioshield is capable of containing the activation products during the radioactive decay process. To prevent surface water seepage, the main floor of the reactor building was covered by a waterproof material and a layer of concrete to make the areas containing radioactive materials inaccessible to people. Two sealed metal boxes that contain detailed information about the structure and contents of the reactor complex (i.e., “time capsules”) were installed, one beneath the concrete that covers the reactor vessel and the other on a wall inside the reactor building. When radioactivity in the reactor decays to safe levels, information obtained from the time capsules will provide adequate records for access to and complete disposal of the reactor vessel.

More than 99% of the radioactive material entombed at the site in 1969 is in the belowground portion of the reactor complex. In 1968, AEC calculated that the radioactivity would decay to levels low enough to allow all safety constraints to be removed by the year 2106. DOE will re-evaluate the total radioactivity of the reactor before the safety constraints are removed.

**Regulatory Setting**

The Piqua site is managed under the LM Decontamination and Decommissioning Program under the authority of the Atomic Energy Act of 1954, as amended. During decommissioning in the late 1960’s, AEC estimated that the entombed radiological materials would reach free-release criteria under Title 10 Code of Federal Regulations, (CFR), Part 20, “Standards for Protection Against Radiation,” in the year 2106. DOE is responsible for long-term custody and stewardship of the entombed radiological materials onsite. In accordance with the Piqua Long-Term Surveillance and Maintenance (LTSM) Plan, DOE performs annual site inspections and conducts radiological surveys per 10 CFR 835, “Occupational Radiation Protection,” to ensure that the entombment remains protective of human health and the environment. The site is owned by DOE and had been leased to the City of Piqua at no cost from 1969 to 2018. The site facilities are currently vacant. When the entombed radiological materials achieve free-release criteria, site ownership will revert back to the city of Piqua.

In accordance with LM’s Cultural Resource Management Plan, LM identifies the site as eligible for listing on the National Register of Historic Places. DOE remains committed to the preservation of cultural resources and maintains the structures onsite in accordance with the National Historic Preservation Act (NHPA).

**Legacy Management Activities**

DOE Office of Legacy Management (LM) manages the Piqua decommissioned reactor site according to a site-specific LTSM Plan to ensure that the concrete and steel entombment structure continues to be protective of human health and the environment. This plan identifies that LM will perform periodic site inspections and conduct radiological surveys of the site. Site inspections ensure that the site remains in a protective state, and verifies compliance with NHPA.

**Contacts**

Documents related to the Piqua, Ohio, Decommissioned Reactor Site are available on the LM website at [https://www.lm.doe.gov/piqua/Sites.aspx](https://www.lm.doe.gov/piqua/Sites.aspx).
